Welcome To DesignBuilder V2025.1

DesignBuilder is a user-friendly modelling environment where you can work (and play) with virtual building models. It provides a range of environmental performance data such as: energy consumption, carbon emissions, comfort conditions, daylight illuminance, maximum summertime temperatures and HVAC component sizes.

Some typical uses of DesignBuilder are:

- Calculating the impact of various design options on building energy consumption.
- Evaluating façade options for overheating and visual appearance.
- Thermal simulation of naturally ventilated buildings.
- Reporting savings in electric lighting due to use of natural daylight.
- Prediction of daylight performance through Radiance simulations.
- Visualisation of site layouts and solar shading.
- Calculating heating and cooling equipment sizes.
- Detailed simulation and design of HVAC and natural ventilation systems including the impact of supply air distribution on temperature and velocity distribution within a room using CFD
- ASHRAE 90.1 and LEED energy models.
- Economic analysis based on construction costs, utility costs and life cycle costs (LCC)
- UK, Ireland and France Building regulations and certification reports
- Design optimisation with multiple objectives, constraints and design variables.
- Life-cycle analysis (LCA)
- Communication aid at design meetings.
- An educational tool for teaching building simulation to architectural and engineering students.

DesignBuilder uses the [EnergyPlus](#) dynamic simulation engine to generate performance data.

Learn About DesignBuilder

If you're new to DesignBuilder you are probably keen to start using the program right away, but there's a few things you should do before you dive in:

- Watch the [Getting Started Tutorials](#).
- Read [Important tips about software use](#).

A few minutes spent with these resources will be time well spent!

There is a range of other freely available learning resources on the [Webinars](#) and [Other Learning Materials](#) sections of the DesignBuilder website.

Recent Files (Opening Screen)

The Recent Files Opening Screen has a list of the files used in your previous DesignBuilder modelling sessions. To access one of these files again you can double-click on it in the grid, or single click in the grid to select it and then 'Open selected site' from the Info Panel on the Toolbar.

You can also:

- [Create a new file \(site\)](#) from this screen.
- Open existing dsb file from the **DesignBuilder Data** folder. This is located beneath the main **Documents** by default.

User Interface

The DesignBuilder user interface has been designed from first principles for ease of use. Each screen has a specific purpose which is described in the Info panel on the right of the screen along with context sensitive commands and other relevant information.

The Info panel is only displayed in [Learning mode](#). If you would prefer to have simultaneous access to the Model Data and the Edit View you can switch Learning mode off from the [Program Options](#) dialog from the Tools menu.

The user interface is described for each group of screens:

- [Opening Screen - Recent Files](#)
- [Opening Screen - Component Libraries](#)
- [Opening Screen - Template Libraries](#)
- [Edit Screen](#)
- [Visualisation Screen](#)

See also the [DesignBuilder User Interface – Modelling: Opening screen, loading a model, screen layout, navigation](#) tutorial

Menu

The DesignBuilder menu is located at the top of the screen and provides a full reference of all the currently available commands.

The following sub-menus are available from the main menu:

- [File](#) - access file operations
- [Edit](#) - options for editing the model
- [Go](#) - options for navigating and obtaining data
- [View](#) - options for adjusting the view of the model
- [Tools](#) - miscellaneous tools
- [Plugins](#) - if you have installed one or more plugin, their menu options will be listed below the top-level Plugins menu item
- [Help](#) - documentation and other support resources on use of the program.

See also: "**Keyboard Shortcuts**" on page **57**

File Menu

The File menu can be accessed from the horizontal [top bar menu](#) at the top of the screen.

Tip: see the "DesignBuilder Model Files" on page 70 help page for advice on file storage, backups etc.

The following options are available when a file is open:

General

- **New file** (Ctrl+N) - create a new DesignBuilder dsb file.
- **Open file** (Ctrl+O) - Open an existing DesignBuilder dsb file.
- **Close** (Ctrl+F4) - close the currently open DesignBuilder dsb file and returned to the opening screen.
- **Print** - Print current view
- **Load results file** - load a [previously generated ESO file](#).

Save

- **Save** (Ctrl+S) - Save currently open DesignBuilder dsb file. If no file is currently loaded then this command saves the libraries.
- **Save without output results** - save the current DesignBuilder dsb file without output results reducing the file size. Use this option if you plan to send the dsb file by e-mail or forums etc.
- **Save as** (F12) - save the DesignBuilder dsb file using a different name/location.
- **Save as template** - save the DesignBuilder dsb file as a template so it can be used as a starting point for subsequent new projects.

Import

- **Import IDF model** - import a model saved in the EnergyPlus IDF file format.
- **Import model from XML** - imports a model previously exported in the DesignBuilder XML model file format.
- **Import component blocks from XML** - imported component blocks and their attribute settings from a file previously exported using the **Export component blocks as XML** menu command.

- [Merge model data from file](#) - import the attribute settings, components and templates, HVAC system, assemblies and component blocks from a previously created DesignBuilder model into a newly modified one.
- [Import 2-D drawing file](#) - import a 2-D DXF floorplan into the model for tracing over.
- [Import 3-D model](#) - import a gbXML model.
- [Import building from external file](#) - import building(s) into the current model from an external file.
- [Import assembly library](#) - imports an [assembly library](#) from an external asl file previously created using the [Export assembly library](#) command.
- [Import library data](#) - import library data from an existing DDF file.

Export

- [Export EnergyPlus Heating design IDF file](#) - export an IDF file using options for heating design calculations.
- [Export EnergyPlus Cooling design IDF file](#) - export an IDF file using options for cooling design calculations.
- [Export EnergyPlus Simulation design IDF file](#) - export an IDF file using options for simulation using hourly weather data.

Note: the IDF export options are only available for fully licensed users. If you are using an evaluation version and would like to test the IDF export tools as part of your evaluation of the software please contact [DesignBuilder sales](#).

- [Export model as XML](#) - exports the model in DesignBuilder XML (dsbXML) model file format. Exported models include all geometry, attribute and custom components and templates, but not results.
- [Export selected component blocks as XML](#) - exports any selected building level component blocks in XML format. The exported file can later be reimported back in either manually through the [Import component blocks from XML](#) menu command or through a [script](#) as part of a parametric analysis or optimisation study. You must be at building level and have component blocks selected to access this command.
- [Export HVAC Loads Report](#) - exports the model in an industry-standard PDF format.
- [Export model image](#) - export the currently displayed image of the model.
- [Export 3-D DXF model](#) - export the model in 3-D DXF format.
- [Export gbXML model](#) - exports the current building geometry in gbXML format including layered constructions, materials, glazing and shading devices for use in another compatible program.
- - exports an IFC file with heating and cooling design results for loading into MagiCAD.
- [Export to MasterClima 11300](#) - exports the current building data in a format compatible with MasterClima 11300. Contact [SGM](#) our Italian reseller for more details.
- [Export CSV report file](#) - export a summary of the model in spreadsheet format.
- [Export assembly library](#) - exports the current [assembly library](#) to an asl file for importing into another model.
- [Export CFD results slices](#) - from the CFD screen, when results are being displayed in slices, this command allows you to export the result values to a csv file for further analysis and checking.
- [Export library data](#) - export library data in DDF format.

Folder

- [EnergyPlus folder](#) - opens a Windows Explorer window in the folder used by DesignBuilder for storing temporary EnergyPlus files.
- [Weather data folder](#) - opens a Windows Explorer window in the folder where the hourly weather files are stored.
- [Library data folder](#) - opens a Windows Explorer window in the folder where library data files are stored.
- [Template projects folder](#) - opens a Windows Explorer window in the folder where dsb file templates are stored. File templates are available for selection on the second tab of the Add new project dialog.

Export DesignBuilder XML (dsbXML)

The **File > Export > Export model as XML** menu command exports the model in DesignBuilder XML (dsbXML) model file format. The exported model includes all geometry, attribute and custom components and templates, but not calculation results. It can be subsequently imported into any other version of DesignBuilder that supports dsbXML.

DesignBuilder XML files have extension .xml.

The [Include library data in exported DesignBuilder XML](#) program option setting can be used to control whether library data is included in the exported dsbXML file.

See also:

- "DesignBuilder XML (dsbXML)" on page 2215
- [Import DesignBuilder XML \(dsbXML\)](#)
- [Include library data in exported DesignBuilder XML](#)

Import DesignBuilder XML (dsbXML)

The **File > Import > Import model from XML** menu command imports a DesignBuilder XML file previously exported using the **File > Export > Export model as XML** menu command.

After loading the file, DesignBuilder automatically saves the imported model in DSB format to the default model folder (usually Documents\DesignBuilder Data). It uses the name of the dsbXML file as a base and appends a number to ensure uniqueness. For example, when importing the file model.xml, the imported mode will be automatically saved as model1.dsb.

Note: When importing dsbXML files into DesignBuilder, any library component and template data stored in the file is replaced with the latest library data. Imported user-defined data is always retained.

See also:

- "DesignBuilder XML (dsbXML)" on page 2215
- [Export DesignBuilder XML \(dsbXML\)](#)
- [Include library data in exported DesignBuilder XML](#)

Export HVAC Loads Report

Select the [File > Export > Export HVAC Loads Report](#) menu option to export combined heating and cooling loads summary data for each zone in an industry-standard PDF report format.

HVAC Loads Options Dialog

First you must make some settings on the **HVAC Loads Options** dialog to define the data to be displayed:

Note: Before selecting the [Export HVAC Loads Report](#) menu option, you should make sure that you have heating and cooling design results already calculated. If this is not the case, you will receive an error message when pressing the OK button on the options dialog.

Project name

This defaults to the building name.

Design alternative

Enter an appropriate name to describe this design alternative.

Heating

If Heating design results are to be included in the HVAC Loads Report, tick this checkbox.

Cooling

If Cooling design results are to be included in the HVAC Loads Report, tick this checkbox.

Totals method

You can sum cooling design total loads in 2 different ways

- **1-Building** - loads are summed for the whole building.
- **2-System** - loads are summed for each [System](#) type allowing you to calculate system (AHU)/block loads for sizing AHUs.

Cooling peak method

Summary cooling design results can be displayed either for the time and month of the overall maximum building cooling load or for the individual zone.

- **1-Non-coincident** - Summary results are for the time and month of maximum cooling load for each zone.
- **2-Coincident** - All summary results are for the time and month of the maximum building total cooling load.

Cooling coincident definition method

When the **Peak method** is set to **2-Coincident** you can specify whether the coincident time for cooling design results is calculated for the building as a whole, i.e. for all zones, or whether it is calculated separately for each system. Select from:

- **1-Building**, where the time of peak cooling for zones is calculated by summing hourly totals for all zones in the building, or,
- **2-System**, where the time of peak cooling for zones is defined considering all zones in each system.

Assessor

Enter your assessor name for the record.

Company

Enter the name of your company.

Viewing The HVAC Loads Report

After pressing the OK button on the HVAC Loads Options dialog you will be asked to provide a filename to save the PDF report.

After saving the report you are asked if you would like to open the report.

If you click "Yes", DesignBuilder will open the PDF report in whatever software is associated with the PDF file extension on your machine.

The "HVAC Loads Report" on page 2102 help topic includes details on the exported report.

Export To MagiCAD

You can export a file in IFC format with heating and cooling loads results for [loading into MagiCAD](#).

About MagiCAD

Fully integrated within Autodesk's Revit and AutoCAD platforms, MagiCAD offers a set of powerful modelling functions for each MEP discipline enabling integrated system calculations. The integration with MagiCAD allows you to feed your DesignBuilder load calculation results back into Revit and from there undertake ductwork and pipework design.

The DesignBuilder > MagiCAD integration works as follows:

1. Export the architectural model directly from Revit by using the native Revit gbXML export.
2. Load the gbXML into DesignBuilder and make any further changes to the model as required.
3. Perform the Heating and Cooling design calculations in DesignBuilder.
4. Export the results using DesignBuilder's **File > Export > Export MagiCAD** menu command. This produces a simplified IFC file containing the results.
5. From within MagiCAD click on the [Import from Design Builder](#) tool. Select the exported IFC file to start the import process. Where the space names and numbers from the active Revit project match the equivalent in the IFC file, the results are loaded to the Revit space instances. In case of mismatches, the spaces can be mapped manually.

Export CSV Report

The CSV report includes an inventory of all the materials, constructions and glazing systems used in the model as well as a summary of each zone with walls, floors, roofs etc, glazing, airflow paths, heating and cooling setpoint temperatures.

Note: The areas of surfaces and openings provided in the CSV report are the same as those that would be used in an EnergyPlus simulation. Under some circumstances these can be very slightly different from the areas specified in the model. For example, in the case where a full height window has top and bottom edges touching the top and bottom of the parent surface DesignBuilder must trim the window slightly to fit it on the surface before providing it to EnergyPlus (and to the CSV report). This is because EnergyPlus requires a small margin between the edges of openings and the host surface. In other words, the edges of child surfaces (openings) cannot be coincident with the edges of the host surface. More specifically, DesignBuilder trims openings where necessary to ensure a minimum margin of 1mm between opening and surface edges.

The report also includes the same [cost](#) and [embodied carbon](#) data that can be obtained from the [Cost and Carbon](#) tab.

To generate the CSV report use the **File > Export > Export CSV report file** menu command. This opens the Report Options dialog with the following settings.

Description

The description to be included within the report.

Report type

The options are:

- **1-Basic** - The basic report.
- **2-ISO 13790** - Same as the basic report but with additional heat flow items included with each line of surface heat transfer data to help with an ISO 13790 analysis.

Edit Menu

The Edit menu can be accessed from the horizontal [top bar menu](#) at the top of the screen.

General

- **Undo** <Ctrl+Z> - undo last operation
- **Redo** <Ctrl+R> - redo last operation
- **End stream** <Enter> - end the partition stream creating a floating partition
- **Cancel current operation** <Esc> - cancel the current operation returning to select mode
- **Undo last point** <Esc> - undo the last point drawn when drawing a block base perimeter or when drawing partitions. Note that when drawing arcs, the **Undo last point** command doesn't undo the whole arc, it operates on one arc line segment at a time. To undo the whole arc, press <Esc> as many times as there are lines in the arc.
- **Clear to default** - clear model data to defaults
- **Load data from template** <Ctrl+L> - loads data from template
- **Reload templates** - reloads data from template throughout model where the template is non-default
- **Transfer blocks** - transfers blocks from one building to another
- **Convert selected outlines to blocks** - convert any selected outlines to component or building blocks
- **Drag block face** - start the drag face operation on the currently selected block
- **Divide block** - divide the currently selected block using the cutting tool
- **Measure** <Ctrl+M> - measure length, angles or areas in the model

Draw

- **Draw block** - add a new block (building level only)
- **Draw internal perimeter** - draw a void/courtyard (block level only)
- **Draw partition** - draw partition streams (block level only)
- **Draw window** - draw windows (surface level only)
- **Draw sub-surface** - draw sub-surface (surface level only)
- **Draw door** - draw doors (surface level only)
- **Draw hole** - draw holes (surface level only)
- **Draw vent** - draw vents (surface level only)
- **Draw construction line** - draw one or more construction lines
- **Place assembly** - place an assembly from the library
- **Flip block surface orientation** - applies only to open manifold blocks imported from BIM models

Remove

- **Remove DXF data** - remove all current DXF data
- **Remove all construction lines** - remove all construction lines
- **Remove all outlines** - remove all outline blocks

Select

- **Select** - returned to select mode
- **Select all** - select all objects in current view

Equipment (zone level, Equipment tab when Detailed gains model option selected)

- [Add](#) - at an item of equipment
- [Edit](#) - edit currently selected equipment
- [Delete](#) - delete currently selected equipment

Opening screen component and template edit

- [Add](#) - add a new component/template as per currently selected item
- [Edit](#) - edit currently selected component/template
- [Delete](#) - delete currently selected component/template

Edit currently selected model objects

- [Move](#) <Ctrl+V> - move selected objects
- [Clone](#) <Ctrl+C> - clone (copy) selected objects
- [Rotate](#) <Ctrl+T> - rotate selected objects
- [Stretch](#) <Ctrl+J> - stretch selected objects
- [Delete](#) - delete selected objects

General

- [Building model options](#) <F11> - open Model options dialog
- [Add building](#) <Ctrl+A> - add a new building (site level only)

Go Menu

The Go menu can be accessed from the horizontal [top bar menu](#) at the top of the screen.

View Menu

The View menu can be accessed from the horizontal [top bar menu](#) at the top of the screen.

Tools Menu

The Tools menu can be accessed from the horizontal [top bar menu](#) at the top of the screen.

General

- [Program options](#) - open program options dialog.
- [Model data grid view](#) - view the model data using a grid view, selecting from a range of view template
- "Optimisation - Parametric Settings Dialog" on page 1707 - **define settings for optimisation and parametric analysis**
- [Rebuild](#) - Rebuilds all secondary geometry including block perimeters, zones, default openings, adjacencies (block and zone) and all display lists from the base building elements.
- [Merge zones](#) - control the way zones are combined.
- [Rezone block](#) - refresh the zoning in the current block.
- [Interzone Airflow](#) - define scheduled air flow rates between zones.
- [Import library components to model](#) - **import current component and template libraries to the model replacing existing ones.**
- [Export data](#) - export results/graphics results from the current screen.
- [Compile report](#) - generation of a report based on previously created [Report topics](#).
- [Hourly weather data](#) - open the hourly weather data dialog.

- [Thermal comfort calculator](#) - calculate PMV and PPD from air and radiant temperatures, RH, clothing and air speed.
- [Show log file](#) - show a log file containing information on your computer and all significant actions taken during the current DesignBuilder session.
- [Building Cost Summary](#) - open the dialog to edit building summary costs.

Results screens

- [Update calculated data](#) - refreshes the results first opening the Calculation options dialog allowing you to enter new options.
- [Lock Y-axis min/max values](#) - locks the extent of the Y-axes so that they keep their current maximum and minimum values allowing consistent comparison with the future results display.
- [Optimisation Analysis Settings](#) - access optimisation settings.
- [View EnergyPlus results](#) - If you are not using the Simulation Manager, this will open the most recently simulated .eso and .htm results into the Results Viewer, or if you are using the Simulation Manager to run simulations, this option will load the most recently loaded set of results for display in DesignBuilder into the Results Viewer.

Libraries (opening screen)

- [Backup libraries](#) - backup component and template libraries
- [Restore libraries](#) - restore previous component and template library backups

Help Menu

The Help menu can be accessed from the horizontal [top bar menu](#) at the top of the screen.

- [Index](#) - access program help using the Index.
- [Search](#) - access program help using the Search facility.
- [Contents](#) - access program help using the hierarchical Contents.
- [Licence](#) - enter serial number and licence keys
- [Tutorials](#) - access DesignBuilder web tutorials
- [About](#) - DesignBuilder version number

Keyboard Shortcuts

Some menu commands can be accessed more conveniently through keyboard shortcut key presses. The tables below provide a list of all of the available shortcuts.

Change screens

<F7>	Edit screen
<F8>	Visualise screen
<F9>	Simulation screen
<Ctrl + F9>	Heating design screen
<Shift + F9>	Cooling design screen

File operations

<Ctrl + N>	New file
<Ctrl + O>	Open file
<Ctrl + S>	Save file
<Ctrl + F4>	Close currently open file
<F12>	Save As

Edit

<F11>	Model options
<Ctrl + F>	Flip Block Surface Orientation

<Ctrl + T>	Rotate
<Ctrl + J>	Stretch
<Ctrl + Z>	Undo last change
<Ctrl + R>	Redo last change
<Ctrl + L>	Load data from template
<Shift + Ctrl + T>	Follow path
<Shift + Ctrl + C>	Remove all construction lines
<Ctrl + M>	Measure tool
<Ctrl + K>	Add block
<Ctrl + B>	Draw partition
<Ctrl + D>	Draw construction line
<Ctrl + V>	Move
<Ctrl + C>	Copy (Clone)
	Delete currently selected data
<Shift + Ctrl + A>	Add building

View

<Shift + Ctrl + F>	Fit view
<Shift + Ctrl + Z>	"Zoom Dynamic" on page 113
<Shift + Ctrl + W>	"Zoom Window" on page 113
<Shift + Ctrl + N>	Pan view
<Shift + Ctrl + O>	Orbit view
<Shift + Ctrl + L>	Look around
<Shift + Ctrl + K>	Walk-through
<Shift + Ctrl + D>	Toggle surrounding block/zone display

View rotation

The [view rotation](#) can be edited using the drop list in the top right of the screen or through these shortcut keys.

<Ctrl + A>	Axonometric view
<Ctrl + P>	Plan view
<Ctrl + ↑>	Front view
<Ctrl + ↓>	Back view
<Ctrl + →>	Right view
<Ctrl + ←>	Left view

Navigation

<F2>	Go up
<F4>	Go to previous object
<F5>	Go to next object

Miscellaneous

<F1>	Context sensitive help
<Ctrl + X>	Export data
<Ctrl + W>	Compile report
<Ctrl + U>	Update results
<Ctrl + Shift + L>	Lock axis

- <Ctrl + Shift + G> Show log file
- <Ctrl + Shift + X> Show file import log
- <Ctrl + Shift + S> Change solar position when on Visualise screen and shadows and the Sunpath diagram are both displayed

Edit Screen

The diagrams below illustrate the various components of the DesignBuilder Edit Screen with [Learning Mode](#) switched on and off.

Learning Mode On

With Learning mode switched on the Edit screen will look similar to the image below.

Use the Model data tabs to access Activity, Construction, Openings, Lighting, HVAC etc [model data](#).

See also the [DesignBuilder User Interface – Modelling: Opening screen, loading a model, screen layout, navigation](#) tutorial

Learning Mode Off

The image below shows the same model but with Learning mode Off. Edit Screen and Model data are visible simultaneously and there is no Info Panel..

DesignBuilder Tips

Miscellaneous information you should know before starting 'serious work' with DesignBuilder:

1. Buildings are put together by [drawing blocks](#). Block creation and edit operations take place at the [building level](#).
2. Blocks can be subdivided into more than one zone by drawing partitions. Partitioning takes place at the [block level](#).
3. Default data is [inherited](#) from the level above, so blocks inherit their data from the building level, zones inherit their data from blocks, surfaces from zones and openings from surfaces. It is therefore possible to make global changes to the model by changing data at building level. It is possible to override default by editing the data. So for example, you could change the external wall construction for a whole block.
4. [Data templates](#) are the source of default data in DesignBuilder. They can also be used for [loading data](#) to the model en masse. For example you can load the 'Energy code - heavyweight' construction template at the building level to change the construction of the entire building to thermally heavyweight elements which comply with local energy codes/building regulations.
5. You can clear non-default data (i.e. data that has been explicitly entered) to its default state by using the [Clear to default](#) command.
6. When drawing a block which touches another block, you should use the shift key to lock the base perimeter to the correct plane before drawing. You can release the shift key once you have placed the first point of the perimeter.
7. Use the snap points - DesignBuilder block geometry is quite easy to work with but you must use the positioning tools provided to ensure that blocks connect exactly. The only way to do this is to use snaps - do not position blocks and partitions relative to each other 'by eye'.
8. Large building models can take a long time to simulate. You should familiarise yourself with the [Working with Large Models](#) help topic before creating a large/complex DesignBuilder model.
9. [DesignBuilder dsb files](#) are already compressed so there is no need to 'Zip' them when attaching to e-mails or support forums.
10. Understand DesignBuilder [constructions](#), in particular the way floors and ceilings are defined.
11. Name your zones. Do this by clicking twice (not double-clicking) on the name in the Navigator and typing the name. This is especially useful when [merging](#) zones and when checking adjacencies of individual surfaces in the Navigator.

12. If you are exporting IDF data for use outside DesignBuilder please read the [Exporting EnergyPlus IDF Files](#) topic.

Core Concepts

Some core concepts you should be familiar with before attempting to use DesignBuilder on a real project are:

- [Model data hierarchy and data inheritance](#)
- [Templates and components](#)
- [Blocks](#)
- [Navigating building models](#)
- [Customising model detail](#)
- "DesignBuilder Model Files" on page 70

Model Data Hierarchy & Data Inheritance

See also the [Model data hierarchy and inheritance](#) tutorial

DesignBuilder models are organised in a simple hierarchy:

Default data is inherited from the level above in the hierarchy, so block data is inherited from building level, zone data is inherited from block data and surface data from zone data. This arrangement allows you to make settings at building level which can become active throughout the whole building; or make settings at block level to change data for all zones/surfaces in the block. So for example, if the External wall construction is set to 'Wall 1' at building level, then this will be the default External wall for all blocks in the building. It is possible to change the inherited defaults in any of these blocks by making an explicit selection (say 'Wall 2'). All the zones in the block whose external wall construction was set to 'Wall 2' have that default External wall construction.

The construction and opening defaults are inherited down to surface level where the data is actually used in the calculations. For example it is the External wall construction model data at the surface level that defines the actual construction used for that external wall. The External wall model data set at zone, block and building level has no effect on the model (other than by providing the default data for the level below in the hierarchy).

To assist in identifying where data is inherited from DesignBuilder uses a colour code. Data set at building level or user defined data 'hard set' at any level below will appear in red. All data inherited at levels below will be in blue (see below).

The simplest way of determining where data is inherited from is to start at the lowest level, a surface or opening, and go up through the levels until the data turns red. This then is the level from which the data has been inherited.

The DesignBuilder hierarchy mechanism is a fast way of setting data globally in a building model, but you must take care to *enter the minimum amount of data* to get the most from the inheritance system. For example if all zones in a particular block have the same activity called say 'Office work', you should set the activity at block level and not multiple times at zone level. Equally if all the blocks in the building have the same activity, you should set the data at the building level and allow the blocks to inherit the data from the building. By keeping the amount of user data to a minimum, you will find it quicker to make changes at a later date. Clearly it is much faster to change a few Model data items at building and block level than it is to make multiple changes at zone or surface levels.

When entering construction data, you could set the construction for each surface in the model but in practice this would be an extremely inefficient process. It is faster and less error-prone to set the construction as high up in the hierarchy as possible, possibly at building level (if all external walls in the building have that external wall construction), or at block level if all walls in that block have the construction (and other blocks don't).

Most data at the building level is 'user data' as buildings do not inherit their data from the site level.

Site data holds location and regional settings as well as a list of buildings.

To undo user defined 'hard set' data run the Edit > [Clear to default](#) menu command and select **All data** or **Custom openings** and specify level (block, zone or surface) down to which the data is to be cleared.

Defaults

In short the rules are:

- [Construction](#) and [Openings](#) data is used at the *surface* level, i.e. all construction and opening data at building, block and zone level is default data and only data at surface level is actually used to define the model.
- [Activity](#), [Lighting](#), [HVAC](#), [Equipment](#) data is used at the *zone* level, i.e. all Activity, Lighting, HVAC, Equipment data at building and block level is default data.

A common question is "*Why do I see Pitched roof constructions at building/block/zone level on the Constructions tab when my building/block/zone doesn't have a pitched roof?*"

The answer is that the Pitched roof construction setting at building, block and zone levels should be thought of as the default setting for any pitched roofs that may (or may not) exist in the model further down in the hierarchy. If there are no pitched roofs in the model then the data is simply not used.

Custom openings

When [custom](#) (user-drawn) openings have been created at surface level these override any openings that would otherwise have been generated through the [facade](#) layout Model data for the surface.

Component blocks

[Component blocks](#) inherit their data from building level.

Partition data inheritance

There are 2 types of partition surface:

- [Partitions](#) separating zones within a single block. These partitions within a block inherit their data from the block level. Why? They can't inherit from zone level because there are 2 zones adjacent to the partition so they inherit from the next level up in the hierarchy - blocks.
- [Inter-block partitions](#) which separate zones in 2 different blocks have 2 parent blocks and so it is not possible for the data to inherit from block level for these surfaces so data inherits directly from building level.

See also: "Zone Level Data for Internal Surfaces" on page 700

Templates And Components

- [Templates](#) are databases of typical generic data.
- [Components](#) are databases of individual data items (e.g. a construction type, material, window pane) .

DesignBuilder allows you to build up your own [libraries of templates and components](#). Note that each user on a computer maintains their own database of templates and components.

Template and component libraries are loaded into your model at the time it is created and new custom data from other computers can be [imported](#) at any time.

Blocks Introduction

[Blocks](#) are the basic geometric shapes that you use to assemble a DesignBuilder model. The idea of blocks is to provide fairly simple objects that you can easily move around in 3-D space in a similar fashion to that of building a physical model using bricks from a construction set. [Blocks are created](#) by drawing 2-D perimeters on horizontal or vertical planes and then extruding these perimeters to form 3-D shapes:

Blocks are versatile objects and once created can easily be modified by moving their surfaces, by [stretching](#) them and even by [cutting](#) them using arbitrary planes. Typically, you might use a block to represent an entire building storey:

Or a particular building design might lend itself to an obvious division into blocks:

You can model an entire building as a single block:

And then cut the block into storeys:

Once the overall geometry of a model has been established with blocks, you can go 'into' a block and sub-divide it into a number of rooms or zones using partitions:

If you sub-divide a block internally using partitions, you can still modify the block by stretching, cutting, rotating, etc. and where possible the internal geometry will be kept.

Also blocks can have boolean geometry operations applied such as [Union](#), where 2 blocks are combined into a single new block, [Difference](#) (subtract), in which one block is subtracted from the other to form a single new block and [Intersection](#), where a new block is formed where the 2 original blocks intersect.

Navigating Building Models

[Quick overview](#) of the navigation tools in action

There are various ways of navigating (moving around) DesignBuilder models:

- Single clicking the appropriate entry in the Navigator panel is the most versatile way because every object in the building has an entry in the Navigation panel. Note that if the [Double click to navigate site](#)

[hierarchy](#) program option is set then you must double-click in the navigator to go to the associated object.

- Double-clicking on the appropriate object in the Edit Screen takes you to it.
- Single-clicking on the appropriate object in the Edit Screen then right mouse clicking on the object and selecting the 'Go to...' menu option at the top.
- Use the [Title / breadcrumbs](#) at the top of the screen to navigate up one or more levels.
- Go to the level up in the hierarchy by pressing <F2> or by right mouse clicking in the Edit Screen and selecting the 'Go up...' menu option.
- The Next <F5> and Back <F4> Navigation buttons allow you to move sequentially through the model (avoiding surfaces). This approach can be slow but can be useful when it is necessary to methodically work through the model for any reason.

The Figure below shows how to either click on the Navigator entry or double-click on the Edit Screen to go to 'Zone 1' from 'Block 1'.

Using The Navigator

The Navigator panel in the top left of the screen includes a full list of the model hierarchy, starting at Site Level and going down to Building, Block, Zone, Surface, Opening Levels. Also included are Component and Assembly Blocks and the HVAC hierarchy when using Detailed HVAC.

The following objects can be renamed by clicking on the currently selected the Navigator Treeview node:

- Site
- Building
- Block
- Zone
- Component block
- Assembly instance
- Solar panel
- High-level HVAC system components (e.g. Loops, Setpoint Managers, Zone groups)

The following objects cannot be renamed through the Navigator TreeView:

- Surface
- Opening (Window, Door, Vent, Subsurface, Hole, CFD boundary condition)
- HVAC system sub-components which only inherit their names from the level above.

Note: The areas quoted in Surface Navigator nodes are gross areas, i.e. they include the areas of any openings they may contain.

Note: The level below Surface in the Navigator includes any openings that are placed on the surface as well as the breakdown of 1 or more adjacencies to other zones or the outside. For example, a floor surface may include two adjacencies: an external floor and an internal floor, as shown in the screenshot below.

See also [HVAC Component Hierarchy and Navigation](#).

Title / Breadcrumbs

The Title at the top of the screen tells you which object you are currently navigated to. For example in the screenshot below the title tells us that we are navigated to "Hallway 1" in block "0 Ground Fl" in building "Art School" on the site "Art School".

The title also acts as "breadcrumbs" allowing you to quickly move up the model hierarchy by clicking on the text in the Title representing the level you would like to navigate to. As you move the mouse over the Title text, the various elements are underlined like a link on a webpage to indicate what would happen if you click with the mouse.

The Title / breadcrumbs are available on all screens, including when editing [Detailed HVAC](#) systems.

Note: Alternative ways to navigate up the hierarchy by one level are by pressing the <F2> key or by right mouse clicking in the Edit Screen and selecting the 'Go up...' menu option.

Customising Model Options

DesignBuilder models can be customised to allow you to enter the level of detail which is appropriate to your building design or modelling project. In early-stage design work you will generally want to use generic selections for most Model Data and so would choose the corresponding 'low data requirement' model options.

As the building design firms up, more information becomes available and you can change the model options to use more specific data tailored to the project and less generic data.

The 'standard' Model Option set is loaded at the point the building is created and you should generally keep these options unless you have specific reason to change.

Model Options are set in the [Model Options dialog](#) from the Edit menu.

DesignBuilder Model Files

DesignBuilder stores all of its main model data in a single file with .dsb extension making it easy for you to send project models along with associated results to colleagues and clients. A .dsb file includes:

- Building geometry
- Model data settings
- HVAC data
- Model components and templates
- Any user-defined weather files
- Any user-defined textures
- All results for Heating design, Cooling design, Simulation, Daylighting, Cost/Carbon, Optimisation and CFD (including all project variations)

See also:

- "Program options - Files" on page 98
- "Data Recovery" on page 2252

Guidance For Working With DesignBuilder .dsb Files

DesignBuilder .dsb files should be saved to and loaded from the local hard disk. You should specifically not work with to the following locations:

1. Dropbox or similar folders which can lock files for synching for storage on cloud servers. **If you try to work on Dropbox or OneDrive folders your data will eventually become corrupted as DesignBuilder tries and fails to save to a locked file.**
2. Network drives. Less risky than Dropbox folders but a risk nevertheless.
3. Removable data sticks.

If you need to store your data using any of the above locations then you should copy your .dsb data stored on the local disk to Dropbox, network or data sticks outside DesignBuilder once you have closed the software down.

Licensing & Activation

[Help menu > Licence](#)

DesignBuilder consists of a modelling Graphical User Interface (GUI) connected to a number of modules each providing a particular functionality. Modules include Simulation, Visualisation, HVAC, CFD etc. You will need a license for each of the modules you intend to use. If you require more than one module then the most

convenient way to obtain DesignBuilder licences is usually to purchase a [DesignBuilder package](#). Each package consists of 2 or more module licences, each module giving access to a particular aspect of DesignBuilder functionality.

There are various types of licence and ways of licensing all accessed from the **Licence Manager** dialog (**Help > Licence** menu option). The types of licence are:

- **Single user** licence which allows you to install DesignBuilder onto a single computer. If you need to use the software on a second computer you can deactivate the licence on the first one and activate on the second. You can move the licence from one computer to another freely in this way.
- **Site network** licence where a site license server is installed on one computer on the network and provides module licenses on demand to DesignBuilder users on the network. With a site network license you purchase individual DesignBuilder modules in quantities sufficient to support your concurrent use requirements.

For details on how to licence the software please read on.

Evaluation

When you first install DesignBuilder you can request an evaluation license to be sent by email. To do this open the Licence Manager dialog and click on the **Evaluate** button (this button will only be enabled if no other licences are loaded on the machine).

This takes you to a new dialog where you can enter your user details including an email address.

DesignBuilder Evaluation

To help us provide you with important information about new products and to access the DesignBuilder support desk, please provide your details. These details will be used to inform you of product upgrades and licence renewals.

Asterisked (*) fields are mandatory

*Email

*Name

Company

*Country

☐ Student ☒ Receive Newsletter

OK Cancel

You will then be sent an email with an activation code. Copy the activation code from the email and return to the Licence Manager dialog, pressing the **Licence** button to open the **Licence Manager Wizard**.

License Manager Wizard

Select the licensing method

Select the method to be used to license the software and click Next to continue

☒ Activation code

☐ License file

☐ Site network license

< Back Next > Help Cancel

Here select the **Activation code** option, confirm your user details and press Next. On the next page paste your activation code into the text box.

Evaluation licences are valid for 30 days from the date of request and allow you to try out a fully functional version of the software to check that it meets your needs and is compatible with your computer. You can read about restrictions with evaluation licences on the [main website](#).

Activation

When you purchase single user licences to use DesignBuilder, you are sent an e-mail containing an 8-character code. You should copy (Ctrl-C) the activation code from the e-mail and follow these steps in DesignBuilder:

Open the **Licence Manager** dialog (**Help > Licence**). Click on the **Licence** button to open the **Licence Manager Wizard**.

Here select the **Activation code** option and press Next.

Enter your user details including a valid email address and press Next.

The image shows a 'License Manager Wizard' window with a 'User Details' section. It contains several text input fields for email, name, company, and country, along with checkboxes for 'Student' and 'Receive Newsletter'. Navigation buttons like '< Back', 'Next >', 'Help', and 'Cancel' are at the bottom.

License Manager Wizard

User Details
Enter your details or use the default, then click Next to continue

To help us provide you with important information about new products and to access the DesignBuilder support desk, please provide your details. These details will be used to inform you of product upgrades and licence renewals.

< Back Next > Help Cancel

On the next page paste your activation code into the text box and press Next.

License Manager Wizard

Activation Code
Enter the Activation Code, then click Next to continue

Activation Code

Paste your activation code in here

< Back Next > Help Cancel

You should see a message to say that the various modules have been activated.

When you press Finish, if the activation was successful, you will be shown the Modules Licence tab displaying the licence status of each module.

Note 1: If you purchased a [Single User Licence](#) then you will be able to activate the code on a single computer.

Note 2: You must be connected to the Internet to activate and deactivate DesignBuilder licenses. If your network has a strict firewall policy then you should ensure that DesignBuilder.exe is allowed to access the www.designbuilder.co.uk website.

Licence file

You may have been supplied with a licence file with extension .lic containing your licence or extended evaluation. Typical reasons for using a .lic file are when on a training course where you may not have access to the Internet for activation or for customers who have purchased licences but either do not have Internet access or have strict firewall policies preventing the standard web-based activation from working.

To activate DesignBuilder modules using a .lic file follow the instructions below. Before starting make sure the lic file you received has been saved to a place where you can access it, e.g. desktop, a pen drive, documents folder etc. The location does not have to be permanent as DesignBuilder will store a copy of the lic file in a safe place on the local machine.

Open the **Licence Manager** dialog (**Help > Licence**). Click on the **Licence** button to open the **Licence Manager Wizard**.

Select the **Licence file** option and press Next.

Click on the browse button, select the Licence file and press Next.

Press the Finish button to complete the action.

Site Network Licensing (client side)

With site network licenses each client computer on the network can "check out" licenses from the license server application which manages the allocation of licenses. The system is designed to provide a maximum number of concurrent users according to the number of seats purchased. For example if you purchased a site licence with 10 seats for the EnergyPlus module then the software can be installed on any number of computers but only a maximum of 10 people will be able to access DesignBuilder EnergyPlus simulations at any one time. If an eleventh person on the network tries to check out an EnergyPlus license (by starting DesignBuilder with EnergyPlus selected in the License dialog) then they will receive a message to say that the seats are all in use and to wait until one becomes available.

DesignBuilder site licensing requires a simple server application to run on the network to provide licenses. Each client computer has a setting to tell the software to run in site license mode and where to find the Licence Server on the network. The site licensing system is quite straightforward but does require a network administrator with adequate IT skills to set it up.

To set up site network licensing on a *client* computer (i.e. the computer that is to run DesignBuilder) follow the instructions below.

Open the **Licence Manager** dialog (**Help > Licence**). Click on the **Licence** button to open the **Licence Manager Wizard**.

Select the **Site network licence** option and press Next.

On the second page enter:

- a. Either the name of the server or its IP address.

The image shows a Windows-style dialog box titled "License Manager Wizard". The main heading is "Site Network Server Method", followed by the instruction "Enter the site network server details then click Next to continue". There are two input fields: "Enter the server hostname or IP address" with the text "dbserver01" entered, and "Enter the port number" with the text "5053" entered. The "dbserver01" text box is highlighted with a red oval. At the bottom, there are four buttons: "< Back", "Next >", "Help", and "Cancel".

You can find the IP address of your server by typing **ipconfig** in the Windows Command box on the server machine.

```

C:\WINDOWS\system32\cmd.exe
C:\>ipconfig

Windows IP Configuration

Ethernet adapter VMware Network Adapter VMnet8:

    Connection-specific DNS Suffix  . : 
    IP Address. . . . . : 192.168.87.1
    Subnet Mask . . . . . : 255.255.255.0
    Default Gateway . . . . . : 

Ethernet adapter VMware Network Adapter VMnet1:

    Connection-specific DNS Suffix  . : 
    IP Address. . . . . : 192.168.254.1
    Subnet Mask . . . . . : 255.255.255.0
    Default Gateway . . . . . : 

Ethernet adapter Local Area Connection:

    Connection-specific DNS Suffix  . : 
    IP Address. . . . . : 192.168.1.16
    Subnet Mask . . . . . : 255.255.255.0
    Default Gateway . . . . . : 192.168.1.254

Ethernet adapter Wireless Network Connection:

    Connection-specific DNS Suffix  . : 
    IP Address. . . . . : 192.168.1.15
    Subnet Mask . . . . . : 255.255.255.0
    Default Gateway . . . . . : 192.168.1.254

Ethernet adapter Bluetooth Network Connection:

```

- b. The port number which will usually be 5053.

When you click the Finish button the connection to the License Server is established based on the port number and IP address you provided on the dialog.

If the site network licence connection was successful you will be shown the Modules Licence tab displaying the licence status of each module.

Once back to the main License Manager dialog you can check out or check back in module licenses through the check boxes in the Use column for each module.

If the server host name or IP address was incorrect, if that server is not running or if the Licence Server service isn't running then the licences will not be accessed and error messages are displayed.

More Detailed Information On Licensing

- [Setting up a Licence Server for Site network licenses](#)

Single User Licences

A single user licence allows you to install DesignBuilder on a single computer. You can move the licence from one computer to the other freely. For example, if you need to use the software on a second computer you can deactivate the licence on the first one and activate on the second.

When you order a DesignBuilder single user license, you will receive an 8-digit activation code in an email. To use this to activate the software follow these steps:

1. Download and install DesignBuilder (if you haven't already done so).
 - a. For **Simulation** work, download from the main [Downloads > Release Software](#) menu option.
 - b. For **UK and Ireland Energy Assessors**, download from the [Downloads > UK Energy Assessors](#) menu option.
2. Run DesignBuilder.
3. In DesignBuilder, open the [License dialog](#) which can be accessed from the top Help menu
4. Press the **License** button
5. On the "Select the licensing method" page, select the **Activation Code** option and press the **Next** button.
6. Fill out your user details including your email address, name etc. and press the **Next** button.
7. On the "Activation Code" page, enter the Activation code. The easiest way to do this is usually to open the email you received with the activation code, copy it so the text is on the clipboard and paste the code into the dialog.
8. Ensure that you have an Internet connection.
9. Then press the **Next** button.
10. This will cause DesignBuilder to automatically download licences for all modules associated with the activation code and activate them. You will then be able to use the software and run functionality associated with each activated license. Press the **Finish** button.

More details can be found in the [License dialog](#) help section.

Setting Up A Licence Server For Site Network Licenses

Site network licenses require a license server application to be installed and run on a server on the network. DesignBuilder runs on the client machines on the same Windows network and obtains licences from the license server on a concurrent basis.

Summary Of Process

In summary, the steps to set up DesignBuilder Site Licenses are:

1. Download the **designb_rlm_v11.zip** file from the [Download > Server Software](#) area of the DesignBuilder website
2. Extract the files in the **designb_rlm_v11.zip** file to the folder on the server to be used to store DesignBuilder site license files (e.g. c:\RLMSERVER)
3. Obtain the License file by clicking on activate.cmd, following instructions on the webpage and saving the license file to the site license folder.
4. Run the RLM server as a service and start the service.

5. On client machines which are to run the DesignBuilder software, open the Licence Manager dialog (**Help > License** menu option) and enter the ip address or hostname of site license server host.

The above steps are detailed below.

Detailed Steps

Obtain your License File

With Site Network Licenses the License file is obtained through the activation code you received when ordering the software.

- a. Before you run the RLM server you will need to obtain your license file and save it into the RLM installation folder. That's the folder containing rlm.exe and other files listed above. We recommend setting up the rlm folder on a local drive on the server itself.
- b. You should have received an activation code from your site license purchase. This is an 8-digit number and is needed to activate the license.
- c. Open the RLM installation folder in Windows Explorer and double click on **activate.cmd**
- d. This loads a web page at www.designbuilder.co.uk with a form for you to enter your activation code.

DesignBuilder
Software **Network License Activation**

Please enter your **activation code** and click **Activate License** to generate the license file.

Activation Code:

Hostid:

IP Address:

Hostname:

This produces a license file activated specifically for your network license server host.
You will need to download the license file and save it for use by the RLM license server.

- e. Other values in the form such as Hostid are automatically filled in for you. After entering your activation code click **Activate License** and if successful you will be presented with a download link for your activated license file.
- f. Download the license file and save in your **RLM installation folder**.

If your server cannot access the Internet

If your server computer has no internet connection then activate.cmd will not be able to connect a browser window to the designbuilder.co.uk web server and you will have to activate manually by following these steps:

1. Open a command window with admin rights on the server.
2. Change directory to the RLM folder (e.g. type "cd \RLM SERVER").
3. Obtain your server hostid by running the command **rlmutil rlmhostid -q 32**
4. Obtain the ip address using the command **rlmutil rlmhostid -q internet**
5. Obtain the hostname with command **rlmutil rlmhostid -q host**
6. Make a note of the **hostid, ip address, hostname** and your DesignBuilder **activation code** and go to a computer with internet connection and run:

https://www.designbuilder.co.uk/license/activate_site.php

7. Enter your details in to the form and download the resulting .lic file.
8. Place a copy of the .lic file in the site license installation folder on your host server.

Running the RLM Server

The server can be run directly by double clicking [rlm.exe](#). This runs a command window and logs activity to the window. This is useful when you first run the license server as you'll be able to see the license server starting up correctly and loading the license file as well as DesignBuilder clients obtaining licenses from the server.

Running RLM as a Service

It is best to set RLM up to run as a Windows service rather than in the command window, otherwise you'll need to remember to manually restart the license server when the computer reboots.

If you are running RLM in a command window you should close that before starting up RLM as a service.

To create the Windows service to run RLM automatically double click on [service_install.cmd](#) or use **Manage Windows Service** in the admin interface.

If the service_install.cmd does not run then open a command window with elevated privileges from Start> right click on Command prompt to run as admin, then cd to RLM folder and type service_install and press Enter key. See below for details.

Note: The service will be added to Windows services but not started.

Use Control Panel > Services to start **DesignBuilder License Server**.

Once started in this way the service will restart automatically if the computer is rebooted. By default the service will write a log file **designb_rlm.log** into the rlm installation folder. If you want this in a different location you can use the admin interface (above) to set up the service then you can specify the service name and the log file location.

You may experience problems with permissions when setting up the service. You can either disable the UAC or try right clicking **service_install.cmd** and choosing "Run as administrator".

Even this doesn't always give you access to the Service Control Manager. You can check this by running a cmd prompt, changing folder to the license server installation folder and running the RLM install service command (below).

If you edit **service_install.cmd** you'll see the command being executed is:

```
rlm -install_service -dlog "%CD%\designb_rlm.log" -service_name "DesignBuilder License Server" -c "%CD%"
```

If you see this error returned "Error: Access to Service Control Manager denied" you can get over this by running cmd as administrator and then run the install command. To do this right click Command Prompt on the start menu and run as administrator. Change folder to the license manager installation folder and run the **rlm.exe -install_service** command given above and it should work.

In case of trouble, add inbound windows firewall rules to server machine, to always allow TCP ports 5053, 5054. If you set fixed ISV port for port-forwarding method of off-site access (See Troubleshooting section)

then also add and fixed ISV port e.g.49670 as an inbound TCP port-allow rule. If necessary, also allow TCP ports 2600 and 2700 inbound.

More information on this can be found in the Reprise License Manager Knowledge base at <https://reprisesoftware.com/knowledge-base>

RLM Server Admin Interface

RLM provides a browser-based administration interface to the license server. To run this, double click on the **admin_interface.cmd** file in the RLM folder using Windows Explorer.

Refer to the RLM End User Manual (double click **online_manual.cmd**) for more details on using the admin interface.

Note: DesignBuilder does not use the Activation page of the admin interface.

Reprise Software, developers of the RLM licensing system, always maintains a current version of the RLM End User's Manual here:

<https://reprisesoftware.com/docs/admin/basics-admin.html>

Adding a lic file for extra seats

If you purchase additional seats for a site network license system, the new licenses are provided in the form of a lic file download. The process of obtaining the additional lic file is the same as described above under [Obtaining your License File](#). The new lic file does not replace the existing lic files, but is used in addition to the existing licenses. The license server reads these multiple lic files, licenses from multiple lic files adding to give the total number of seats of concurrent use that are allowed.

Setting up Client Machines

This steps involved in pointing client machines to the License Server is described on the main [Licensing & Activation](#) page. From DesignBuilder you can check out or check back in module licenses using the License Manager which can be accessed from the Help menu.

Troubleshooting

Unreachable server

Normally when the Client machine can't see server it displays "-17 communications error" and "-111 Connection refused at server". In that case the access to the server is probably being blocked.

The RLM Licence server uses random ports. So, the best solution is not to allow exceptions by port, but instead by program, eg. open all ports used by "rlm.exe".

But if the server is behind a firewall that you have to specify pinholes to get access then follow these instructions:

In order to specify what port the second service uses you will have to edit the lic file.

On the ISV designb line of the lic file (that will be the 2nd line) add the following:

- port=nnnnn
- where nnnnn is the port number. There must be a space before the word "port".

Usage of licence server from off-site (via WAN)

Method 1: VPN with a sufficiently fast connection.

The remote user will need to login through your VPN connection and access the server that is hosting the network license. DesignBuilder site licence is IP based.

Method 2: Port forwarding

After activating the site license activation code, download the .lic license file, open the file in a text editor, with admin rights. Example:

```
HOST localhost 780bc61a  
ISV designb port=49670  
LICENSE designb designbuilder_n.
```

Now, on the second line you should see "ISV designb" but the "port=..." part is probably not present.

Be sure to insert after "designb", a space, followed by "port=", followed directly by a port number – one example is 49670.

Then save the lic file and restart the service.

This instructs the licence server to use a fixed "ISV port" as specified, instead of randomly choosing the port number from a range each time the server is started (default behaviour, good for security but it makes port-forwarding for off-site access unachievable).

In the router used by the licence server, set up port forwarding from WAN TCP port 5053, to LAN TCP port 49670 or whatever you chose as your fixed ISV port. Forward to the LAN static IP of the licence server machine.

All clients, whether on LAN or WAN, must then access the server using port 5053. When on WAN, for host name they must use the server's WAN static IP or DDNS host address as the host name. This means when a staff member moves in/out of the office with their laptop, they have to switch the hostname in their DesignBuilder (client) licence settings (unless you have something clever set up on your network to make this seamless). The VPN approach is probably more convenient in this respect.

Note: It is the customer's responsibility to consider security concerns when opening ports etc.
DesignBuilder Software Limited shall not be held responsible for damages due to a security breach.

The DesignBuilder licence server is based on the Reprise Licence Manager (RLM) software in case you have prior knowledge of this platform.

Program Options

The Program options dialog is accessed from the [Tools menu](#).

The Program options apply to the overall application no matter which file is loaded. There are six tabs:

- [User interface](#)
- [Dialogs](#)
- [Files](#)
- [EnergyPlus](#)
- [Limits](#)
- [International](#)

See also the [Program and Model Options](#) tutorial

Program Options - User Interface

User Interface tab of the [Program options](#) dialog

Learning

You should generally select **Learning** mode while you gain experience with DesignBuilder. In Learning mode, the [Info panel](#) is shown to the right of the main screen, providing additional information and commonly used tools relevant to each screen. Model data is accessed from tabs along the top of the screen.

With Learning mode switched off, the Info window is not shown and Model data is shown on the right of the screen alongside the Model edit screen. This allows you to see the effects of updates to data as they are made. The Program help commonly refers to this setting as "non-Learning mode".

See the [New Project and Learning Mode Tutorial](#)

Help system

Select one of:

- **1-Web-help** - the default option where the latest help is displayed from the DesignBuilder servers using the **Web Help** system. This option has the advantage of providing the most up-to-date help but it requires an Internet connection and is slower than...
- **2-Local help** - a chm format help file called **Manual.chm** is downloaded. Once the help file is downloaded no Internet connection is required for help.

Technical details on the 2-Local help option

When using **2-Local help**, the help file is called **Manual.chm** and is downloaded and stored on the local hard disk at:

C:\Users\<Username>\AppData\Local\DesignBuilder\Help\V6.0

You can download the help file once while you have an Internet connection and manually copy it to other computers as required when on or off-line, remembering to select the **2-Local help** Program option on the other computers.

Use Slider controls

Some significant data items are (by default) controlled using a 'slider' which allows rapid selection of typical values. If however you need to enter precise values (for example when modelling an existing building) or if you need to enter values outside the slider range you may prefer to type this data in a text box. In this case uncheck the 'Use slider controls' data. Common reasons for this are to enter [Computer gain](#) densities for IT suites or dealing rooms.

Note: when using DesignBuilder with [IP units](#), slider controls are always switched off regardless of this setting.

Sort lists

By default DesignBuilder automatically sorts navigator and other data lists alphabetically. This can make it easier to find the data you are looking for but also increases the time taken to generate lists and so slows some program operations requiring lists to be generated. You can request unsorted lists by unchecking this option.

Line smoothing in the display

DesignBuilder can optionally smooth lines in the Edit screen to provide a crisp clear view of axes, North arrow, construction lines etc without 'jaggies'. Note that this option does not affect the surfaces of the model itself.

On some less powerful computer displays, some line types in the model edit screen can be hard to see with this option selected. You should ensure that this option is unchecked if you have this problem on your computer. The default setting is off.

If you have a good quality graphics card you may prefer to leave this option unchecked and switch on hardware antialiasing on the control panel provided by the software that comes with the graphics card. This will improve image quality without the need to change DesignBuilder settings.

Automatically refresh site navigator lists

By default DesignBuilder automatically refreshes the contents of the site navigator list on the left of the screen as the building is modified so it is in synch with the model. However, when working on large models, frequent rebuilding of the navigator list can slow progress especially when drawing partitions or renaming zones. You can uncheck this option to avoid this problem.

Warning: You should be careful when using this option as the Navigator list can quickly become out of date when you are editing a model. You should be especially wary of clicking on objects in the Navigator which no longer exist in the model as this can cause DesignBuilder to crash. For this reason **we can only recommend unchecking this option for advanced and "careful" users!**

You can manually refresh the navigator lists by clicking on the [refresh list](#) icon above the Navigator panel (below).

Double click to navigate site hierarchy

By default you can navigate to an object in the site hierarchy (building, block, zone etc) by single-clicking in the Navigator. You can change this behaviour by checking the [Double click to navigate site hierarchy](#) program option. In this case you must double-click to go to objects in the Navigator and a single click highlights the object in the Edit view (if you are already at the level above). For example if you are at block level and you single click on one of the zones in the block the zone is highlighted in red in the Edit view.

Tip: Enabling this option can be useful for identifying blocks, zones, surfaces by single-clicking in the Navigator. It can also save time when renaming many zones at once from block level as it becomes possible to click on the zone Navigator entries to rename them without navigating down to each zone and then having to navigate back up again to block level to rename the next zone.

Show 'Load data from template' dialog when template selected

When you select a new template by clicking on the browse button in the Model data, by default the data in the template is loaded directly to the current object. However if this option the 'Load data from template' dialog is opened giving you the opportunity to select various options and load other templates. This option is switched off by default.

Show model data departures from template in bold

Select this option to show any differences in model data relative to the selected template in bold. This option is switched on by default.

Default surface normal view

When working at [surface level](#) it can be useful to get a normal view of the surface by clicking on the [Normal button](#) in the top right of the screen. By default this will show a normal view of the surface as viewed from **outside**. You can use the **Default surface normal view** program option to instead view from the **inside**.

Maximum characters shown in data display lists

You can control the number of characters displayed in data lists on the right hand panel. This provides a workaround to a problem with the list component used in DesignBuilder which always scroll to the right when an item with a long name is selected. This scrolling can be inconvenient so we have implemented the option to control the amount of text displayed. By default this is set to 35 characters but you can use a larger value if you prefer.

Show tooltips in Model data

With small window sizes or when Learning mode is switched off there is not always enough space to display the caption for each Model data item so DesignBuilder provides the option for tooltips to appear when the mouse hovers over a truncated caption. See screenshot below.

Show attribute names in tooltips

When the **Show tooltips in Model data** option is active you can choose to display the names of model attributes in tooltips that appear over user interface items. These may need to be accessed when writing EMS, CS-Script and Python scripts and plugins.

Tip: A full list of all model attributes can be found in the [Extensibility Tools User Guide](#).

Colour scheme

You can control most of the colours used in the DesignBuilder user interface by selecting from a list of pre-defined Colour schemes. The screenshots below show how the 3 Colour schemes provided with DesignBuilder look when loaded.

Classic (Default scheme)

Architectural light

Architectural

Tip: To further customise the appearance, you can create your own Colour scheme and select that. When creating your own Colour scheme, it is best to start by copying one of the existing schemes and editing the copy.

Program Options - Dialogs

Dialogs tab of the [Program options](#) dialog

Auto calculate

Check this option if you prefer DesignBuilder to automatically start calculations (typically opening the calculation options dialog first) when you move to a new calculation tab. For example when you click on the Simulation screen and there aren't any results available to display yet, by default DesignBuilder shows the Update button, giving you opportunity to update the results. However if you activate the **Auto calculate** program option, DesignBuilder will instead open the Simulation calculation options dialog. This was the default behaviour in v5.1 and earlier, but in v5.2 and later it is necessary to click on the Update button to start a calculation.

Calculation dialogs

These options control whether a calculation option dialog appears by default before every calculation. Note that a dialog always appears when you press Update.

New Object Dialogs

New project

When you create a new site (project), a dialog box appears by default allowing you to enter basic data on the new project. If you prefer not to see this dialog in future and just use default data, uncheck this checkbox.

New building

When you add a new building, a dialog box appears by default allowing you to enter basic data on the new building. If you prefer not to see this dialog in future and just use default data, uncheck this checkbox.

Reports

Default report destination

When you export data (typically by clicking on the [Export](#) toolbar icon) there are 3 options for the destination of the report. You can define which option you most frequently use by choosing from one the available default options:

- **1-File** - save the data as a file.
- **2-Clipboard** - copy the data to the clipboard for pasting into another application such as Word or Excel.
- **3-Report topic** - store the data as a [report topic](#) which can later be included as a page in a report by using the [Compile report](#) option.

EN ISO 673 Glazing U-value Calculations

There are some options for the calculation of the U-value according to EN ISO 673.

Fixed mean gas temperature (10°C)

You can choose to fix the mean gas temperature to 10°C which is the requirement for strict adherence to EN ISO 673. Unchecking this option allows the gas temperature for each gas layer to be calculated individually for a more accurate calculation of gas conduction (and hence the glazing U-value) to be made.

Outside air temperature

You can define the outside air temperature to be used as boundary conditions in the calculation of glazing U-value. The outside air temperature should be 0°C for strict adherence to ISO 673.

Inside air temperature

You can define the inside air temperature to be used as boundary conditions in the calculation of glazing U-value. The inside temperature should be 20°C for strict adherence to EN ISO 673.

Detailed HVAC

Default HVAC zones target

By default in Detailed HVAC when you edit an HVAC zone equipment object, such as an HVAC zone, a FCU a chilled ceiling or a sub-component within zone equipment such as a zone heating coil, any changes made on the dialog apply only to that object. That is **1-This HVAC Zone only** is selected by default on the [Target tab](#) of the dialog. However you can use this selection to choose a different default option allowing changes made to be saved to the equivalent component in all HVAC zones in the group by default if that is what is required. Options are:

- **1-This HVAC Zone only** - the data on the dialog will be saved for the current HVAC zone only.
- **2-Multiple (all settings)** - all of the data on the dialog will be saved for all HVAC zones in the group
- **3-Multiple (modified settings only)** - only the changed settings on the dialog (shown in red) will be saved for all HVAC zones in the group.

Show HVAC zone default data on the HVAC zone group dialog

When an HVAC zone is added to an HVAC zone group, default values are taken from the HVAC zone group. This default HVAC zone group data is normally hidden because it can confuse new users who expect changes made to HVAC zone default settings on the HVAC zone group dialog to be inherited by child HVAC zones.

This option allows more experienced users who understand that the HVAC zone group defaults are only used at the point when the HVAC zone is added to the group to control defaults. It is switched off by default.

Tip: The most important application of HVAC zone group default data is when [saving HVAC templates](#) where specific HVAC zone settings are required. Any HVAC zone settings made in the source model are not saved with an HVAC template, but the settings on the HVAC zone group are saved and applied to zones added to the HVAC zone group when the template is subsequently loaded in the destination model.

Hideable Messages

Confirm object deletion

Check this option if you would like DesignBuilder to prompt you to confirm before deleting any objects in the model. You may need to use this option if you have previously checked the checkbox on the delete object dialog (below) and would now like to change back to the default behaviour of confirming before deleting.

Program Options - Files

Files tab of the [Program options](#) dialog

Backup

DesignBuilder will by default make automatic backups of your current working file. Check the **Automatic backup** option box and select a backup interval to enable this option.

DesignBuilder copies the auto backup file to the [Backup](#) folder below [DesignBuilder Data](#) folder.

See also [Data recovery](#).

Note: DesignBuilder keeps files in the [Backup](#) folder for up to 30 days and removes old backups each time the program is run.

Saved Models

Save DesignBuilder library data to models

Warning: Switching this option on causes the entire DesignBuilder library to be stored in every dsb model file that you save. This will cause dsb files to become larger than they need to be. This option should normally be switched off. You should only switch it on if advised to do so by DesignBuilder Support.

DesignBuilder XML Files

Include library data in exported DesignBuilder XML

This program option setting can be used to control whether or not library data is included in exported dsbXML files. Available options are:

- **1-None** - the default option, excludes library data from the XML, resulting in significantly smaller file sizes.
- **2-All** - includes all library data in the XML, resulting in a self-contained data set but a very large file size.

When exporting for subsequent importing to DesignBuilder v2025.1 and later, you should generally use the default **1-None** option to minimise the file size. In this case, only user-defined components and templates are stored in the exported file.

If, on the other hand, the file is intended for loading into a 3rd party tool or into DesignBuilder v7.3 or earlier, you should generally use the **2-All** program option to include all library data in the tables. This ensures that data for all components and templates referenced within the model is included in the XML, making the data set self-contained. The dsbXML file size can be very large when including all library data.

Note: Library data is identified as any component or template in a data table with an Id value of less than 10,000. User-defined custom data, on the other hand, has an Id of 10,000 or more. Custom data is always exported regardless of the program option setting.

See also:

- "DesignBuilder XML (dsbXML)" on page 2215
- [Export DesignBuilder XML \(dsbXML\)](#)
- [Import DesignBuilder XML \(dsbXML\)](#)

Default Folders

DesignBuilder stores the most recently used folders for:

- Data file storage - default folder for .dsb .skh and .ddf exports.
- Picture file export - default folder for pictures and movie exports.
- Report file export
- DXF file import/export

You can edit these default folders on this tab.

Program Options - EnergyPlus

EnergyPlus tab of the [Program options](#) dialog

EnergyPlus

EnergyPlus version

You can select the version of EnergyPlus to use in your simulations. This can be useful to target a specific version you may wish to use or when a new version becomes available which might provide new functionality or address previous problems.

Tip: You should generally use the recommended DLL option as it is tightly integrated with DesignBuilder and provides progress feedback.

DesignBuilder comes with 2 internal versions of EnergyPlus:

- **DLL** - the default option, runs the internal version of EnergyPlus supplied with the program asynchronously giving visual feedback of progress and allowing interaction with the computer during the simulation.
- **Executable** - an executable version of the program running in a command window.

Alternatively you can select an [executable version of EnergyPlus supplied by DOE](#). If you are [exporting IDF data](#) for use outside DesignBuilder you should select the appropriate DOE version to avoid [incompatibilities](#).

Note: the EnergyPlus version selected here is used for simulations within DesignBuilder but also as the target version when exporting IDF data for use outside DesignBuilder.

Mode

If you select an executable version (internal or DOE) there are four options available to control the way EnergyPlus is executed when simulating within DesignBuilder:

- **1-Executable (minimised)** - runs the executable invisibly - you will just see a minimised window on the Task bar but not the EnergyPlus command window.
- **2-Executable (visible)** - runs the executable showing EnergyPlus screen output in a command window.
- **3-Executable (debug)** - runs the executable showing EnergyPlus screen output in a command window and pauses after simulation - intended for advanced EnergyPlus users who may want to see the stack dump following a crash.
- **4-Executable (EP-Launch)** - runs the DOE-supplied EP-Launch program, waiting until this is closed before loading results. This option is only possible if you have selected a DOE-supplied version of the EnergyPlus executable. This option can be useful for making quick minor changes to the IDF data prior to simulation. Any changes made to the IDF data from within EP-Launch will be included in the simulation but will not be retained for future simulations. **Info on the EP-Launch option.**

The screenshot below shows EP-Launch being used to control EnergyPlus simulations from DesignBuilder.

Note 1: If you use this method you must make sure to set the correct weather file manually.

Note 2: Any changes you make to the IDF data, either in the IDF Editor or using a text editor, will be saved in a file called ip.inp in the EnergyPlus folder. This file will be overwritten the next time a simulation is requested so if you wish to save any changes you make to IDF data you should use the File > Export option and edit the data and make simulations outside DesignBuilder.

Note 3: If you want to run EnergyPlus without DesignBuilder then use the File > Export > Export EnergyPlus IDf file > Simulation option to generate the idf file and load this using EP-Launch outside DesignBuilder.

EnergyPlus export folder

When using a DOE EnergyPlus executable version you must also select the folder where the selected version is installed.

When you select any option other than the default DLL option, the necessary EnergyPlus files are downloaded seamlessly prior to the first simulation following the change.

Note: If you wish to install a different DLL version of EnergyPlus to that which is recommended, you must have administrative rights on the computer.

DesignBuilder are licensed distributors of EnergyPlus. All versions of EnergyPlus supplied by DesignBuilder have been compiled by the DOE.

Running a DOE Version of EnergyPlus

To run a version of EnergyPlus downloaded from the DOE website you should create a new [EnergyPlus version](#) using the **Custom** category and make the appropriate settings. The screenshot below shows the EnergyPlus tab on Program options in this case.

When doing this it is important to consider that the only versions officially supported by DesignBuilder are the ones in the DLL list, and of those, the only one that has been fully tested is the default DLL option. The other options provided should generally work but no guarantees are provided. You may also be able to create and use new custom EnergyPlus versions not listed under the DLL category *if the IDF /ESO file input/output formats are the same as one of the options provided by DesignBuilder*. In this case you should look out for possible problems with simulations not running or results not loading correctly.

Output File

Output file format

This option allows you to define the format of the EnergyPlus Summary "CSV" output file. Select from:

- **1-Auto** - the default option where DesignBuilder selects either the appropriate option based on the machine locale. Normally it will use the tab format for machines using

- **2-Tab** - ensures that EnergyPlus generates a file called eplustbl.tab in which the tab character is used to separate the values, regardless of the machine locale.
- **3-CSV** - ensures that EnergyPlus generates a file called eplustbl.csv in which the comma (,) character is used to separate the values, regardless of the machine locale.

Save ESO simulation output

The ESO file is the primary output from EnergyPlus used by DesignBuilder to access simulation results. ESO output files will be generated by EnergyPlus following Heating design, Cooling design and Simulation calculations. You should normally leave this option checked to ensure that results are generated.

If you choose to **Save ESO simulation output** then you can also select options to **Prompt for filename** and **Auto load ESO** described below.

Note: These three settings only apply when the Simulation Manager is not being used.

The ESO files can be loaded later using the File > [Load results file](#) menu option, provided the model hasn't changed too much. In this case the rules are as follows:

1. The DesignBuilder model must still have same zones and surfaces it had at the time the simulation data was generated
2. If you have modified these files and carried out further simulations in EnergyPlus you should find that the results will read in OK provided you haven't changed zone or surface names in the IDF data.
3. You cannot read in ESO files generated from IDF data which was entered by hand (or by other software) because the zone and surface references will be different.
4. Results must be loaded to the correct screen - you can't for example read Heating design results into the Simulation screen.
5. *Simulation only:* the results to be read in must have been generated using the same [simulation period](#) and number of [timesteps](#) currently set in the [Simulation options](#).

Prompt for filename

Tell DesignBuilder whether you wish to be prompted for a filename after each simulation. If you choose not to be prompted then DesignBuilder will automatically generate output filenames based on the name of the dsb file, the calculation type, the [calculation description](#) and the date. It places the file in the [EnergyPlus folder](#). If you choose to be prompted the file can be stored anywhere on your computer system.

Auto load ESO

Check this option to automatically load the ESO results file after simulations. If you have been warned that there will be a lot of data and the program may crash on reading results you may wish to switch this option off and reload the results later. It is often possible to read in very large ESO files after DesignBuilder has restarted following a simulation and this can be a useful for avoiding a crash due to too much data. You may also wish to switch the option off to avoid waiting for the results to read in when carrying out parametric simulations.

This option only refers to Simulation results not to Heating/Cooling Design results.

IDF Options

Store IDF files

When this option is checked the EnergyPlus IDF input file associated with the simulation is stored with model and can be accessed later even after the file in the EnergyPlus folder has been overwritten. This option is off by default to help conserve memory for other operations.

Display extra warnings

Requesting Display extra warnings causes the statement:

Diagnostics, DisplayExtraWarnings;

to be included in the IDF data. This option is intended for use by experienced EnergyPlus users who understand the significance of the extra warning messages generated.

IDF Formatting

The IDF data can be formatted using the options:

- **1-Full** - all indentation and comments are included in the IDF data and user-defined names are used as object identifiers. You should avoid this option for very large models as the amount of text generated can cause issues with memory.
- **2-Basic** - the default option where indentation and some minimal comments are included in the IDF data. Choose this option if your model is large but you would like to retain user-defined names in the IDF object names.
- **3-Compressed** - the IDF data is fully compressed by removing indentation and comments and most user-defined names are replaced with numeric identifiers. Choose this option if your model is very large and you wish to reduce the amount of IDF text being processed. When the IDF data uses more than about 10MB of disk space DesignBuilder is unable to process the quantity of text involved and if this happens when the **1-Full** or **2-Basic** options are set it will attempt to regenerate the IDF data using the **3-Compressed** option to reduce the memory requirement. If IDF data is being generated twice before your simulations you can speed the process by selecting this option from the start ensuring that IDF data is only generated once.

IDF Object Naming

IDF name type

Normally DesignBuilder uses human readable names in the IDF based on the names used in the model. However you can override this behaviour by changing this option. Select from:

- **1-User-defined** - the default option where human readable user-defined names are used wherever possible in the IDF data.
- **2-Numeric** - where machine-generated numeric IDs are used instead of readable names used in the model.

Note: If you are using an evaluation licence then the software behaves as if the **2-Numeric** setting has been selected, regardless of the selection here.

Use material, construction and zone name names in IDF

You can override the overall way that IDF names are written specifically for materials, constructions and zones by checking/unchecking this checkbox.

Distance Between Site Location And Weather File

Check distance between site location and weather file

The locations defined by the site location (latitude and longitude) should match with that of the Hourly weather file. If you would like DesignBuilder to enforce a minimum distance then check this option.

Maximum allowed distance

If the above **Check distance between site location and weather file** option is checked then enter the maximum distance allowed between the location defined by the [site latitude/longitude](#) and the [latitude/longitude set for the Hourly weather file](#) here (in m or ft). The default setting is 200,000m i.e. 200km.

Using Custom Versions Of EnergyPlus

If you have compiled a special version of EnergyPlus you can use it to run simulations from within DesignBuilder by following the instructions below. Note that the custom version must be based on one of the versions supported by DesignBuilder and ideally the default version. The instructions are easiest if the version number of your custom compilation is the exactly the same as that of a version that is supported by DesignBuilder.

When the custom version has the same version number as a supported version

1. Recompile your new version of EnergyPlus into EXE form (not DLL)
2. Select the EXE option from the EnergyPlus program options corresponding to the custom version.
3. This downloads and installs the appropriate standard version of EnergyPlus from the DesignBuilder servers to the DesignBuilder [EnergyPlus folder](#) (if it hasn't already been downloaded).
4. Copy your custom EnergyPlus.exe (and Eplus+.idd if this has changed) to the DesignBuilder [EnergyPlus folder](#) overwriting the standard the files downloaded by DesignBuilder.
5. Test by running simulations from within DesignBuilder to ensure that your custom version is being run.

When the custom version has a new version number

1. Follow instructions 1-3 above selecting the standard version most similar to your custom version. This ensures that all standard files are installed ready to be overwritten with custom files.
2. Create a new version component from the EnergyPlus tab on the Program options dialog and enter the custom version on the dialog. See below.

3. Copy all of the EnergyPlus files which have changed typically EnergyPlus.exe and Energy+.idd to the DesignBuilder [EnergyPlus folder](#).
4. Test by running simulations from within DesignBuilder to ensure that your custom version is being run.

Program Options - Limits

Limits tab of the [Program options](#) dialog

Maximum number of circle segments

DesignBuilder does not work with circular objects directly. Instead, any circular perimeters, openings etc drawn are converted to a stream of line segments to represent the circle. DesignBuilder prevents you from generating circles with more segments than this user-defined setting.

Note: you are advised not to exceed the default setting of 32 to prevent overly complex objects from being created.

Maximum number of arc segments

DesignBuilder does not work with arc objects directly. Instead, any arc segments in perimeters and openings etc are converted to a stream of line segments to represent the arc. DesignBuilder prevents you from generating arcs with more segments than this user-defined setting.

Note: you are advised not to exceed the default setting of 32 to prevent overly complex objects from being created.

Maximum name length

This is the maximum length of name in characters for materials and constructions. If DesignBuilder finds names longer than this it will prevent any calculations requested.

Maximum EnergyPlus ESO file size for importing hourly and sub-hourly results (KB)

Before DesignBuilder starts loading an EnergyPlus result set from an ESO file it checks the size of the file. If the file is larger than the value entered here in KB then you will be prevented from loading hourly and sub-hourly results from the file. In this case you will be asked whether you would like to load the results without hourly and sub-hourly results and if so the load continues but hourly and sub-hourly results will not be available for viewing. If you select "No" then the load is cancelled and no results will be available.

This safeguard has been included to prevent users from attempting to load excessively large datasets that could cause the software memory limits from being exceeded.

Program Options - International

International tab of the [Program options](#) dialog

Language

DesignBuilder currently supports 5 languages:

- **English** - native language of DesignBuilder
- **Italian**
- **French**
- **Spanish** - available only from our Spanish speaking representatives [Aurea Consulting \(Spain\)](#), [Sol Arg \(Mexico\)](#) and [Energy Arg \(Chile\)](#)
- **German**

When you change the language you must restart DesignBuilder for all screens and dialogs to be refreshed.

Units

Units

Two options for units are available:

- **1-Metric (SI)** units and,
- **2-Inch-Pound (IP)** units.

Because the program uses SI units internally, and because the databases which come with the program have mainly been built up using SI units, US users may find some limitations with the user interface when in IP mode. For example the [sliders](#) used on some dialogs are replaced by text boxes.

Currency

Currency

Select the [currency](#) to be used in all cost model data and economic calculations. This setting is used to localise all cost calculation results.

Filters

Region filter

The region filter allows you to see only the data relevant to your particular region. Note that if you have a file loaded then DesignBuilder will use the region associated with the location of the site. The region in this dialog is only used when no file is loaded. Data tables which can be filtered in this way are:

- Constructions
- Glazing
- Materials
- Metabolic rates
- Schedules
- Holidays
- Activity templates
- Construction templates
- Glazing templates
- Lighting templates
- HVAC templates
- DHW templates
- Sectors

Show ASHRAE data

Check this option if you would like to be able to view and access ASHRAE components and templates in tables listed below.

- Constructions
- Glazing
- Materials
- Schedules
- Activity templates
- Construction templates
- Glazing templates
- Lighting templates

Show NCM data

Check this option if you would like to be able to view and access components and templates that are specifically associated with the England and Wales region.

Show Spanish data

Check this option if you would like to be able to view and access components and templates that are specifically associated with the Spain region.

Show other region data

Use this option to display/hide component and template data from other regions.

Show 'General' data

Use this option to display/hide component and template data from the 'General' region. Options are:

1-Never - never show General data

2-Always - always show General data

3-When no region specific data - only show General data when there is no region specific data available.

Show program 'Early' data

Use this option to display/hide special 'Early' and other 'broad-brush' typical system component and template data. Options are:

1-Never - never show 'Early' data

2-Always - always show 'Early' data

3-When no region specific data - only show 'Early' data when there is no region specific data available.

Note: When categories of data are hidden using the program options described above this does not mean they are deleted from the database - the data is still there but it does not appear on lists.

Italian Law

When this option is checked construction layer thickness values are exported to XML in a way that is consistent with Italian Law requirements. This option only affects R-value layers when using the [Export to MasterClima 11300](#) menu option.

Building Models

The process for creating a new building model typically follows a sequence:

1. [Create new site.](#)
2. [Create new building.](#)
3. [Draw and manipulate building blocks to create building geometry.](#)
4. [Partition building into thermal zones.](#)
5. Set [Model Data](#).
6. [Add any 'custom openings'](#) (windows, doors etc) by drawing up the surface level.
7. Size heating and cooling systems.
8. Check design by carrying out summer and winter simulations displaying hourly data.
9. Once model has been checked over short periods, you can use it with confidence for annual simulations.

Create New Site

You can create a new site (dsb file) from the Opening screen. In DesignBuilder, the term 'Site' is synonymous with the file or project because each file can only contain one site. When you request a new site, the **Add New Site** dialog is opened which allows you to select the location and a template:

- [Location](#)
- [Template](#)

See also the [Starting a New Project](#) Tutorial.

Create New Site - Location

Select the Location Template as a source of location and weather data for the site.

The Location defines the geographical location and weather data for all buildings on this site. You will be able to load data from other location templates or override the default data from the Location Model Data tab at Site level.

Create New Site - Template

You can either select 'Blank' to create a clean site, or select a template to base your site on an existing site.

If you have a DesignBuilder file you would like to use as a template for future sites save or copy it to the ['Templates'](#) folder (accessed from the **File | Folders | Template projects** menu command).

Building Geometry

This section describes the various facilities within DesignBuilder to create and edit model geometry.

- "View Controls" on page 110
- "Perimeter Drawing Options" on page 119
- "Snaps, drawing guides, protractor and Grids" on page 123
- "Construction Lines" on page 144
- "General operations" on page 149
- "Importing Geometric Data" on page 162
- "Exporting Geometric Data" on page 183
- "Working with Buildings (Site Level)" on page 184
- "Working at Building Level - Blocks and Solar Collectors" on page 187
- "Working at Block Level" on page 254
- "Working within Zones (Zone Level)" on page 270
- "Working with Surfaces (Surface Level)" on page 272
- "Edit Openings at Building Level" on page 251
- "Undo/Redo" on page 286
- "Rebuild" on page 287
- "Rezone Block" on page 287

View Controls

A range of view controls are provided to allow you to change the point of view for the model and how the model is to be shown on the screen:

- [View Rotation](#)
- [Orbit](#)
- [Zoom](#)
- "Zoom Dynamic" on page 113
- "Zoom Window" on page 113
- [Fit view](#)
- [Pan view](#)
- "Normal View" on page 114
- "Walk-Through" on page 115
- "Look Around" on page 115
- "Surrounding Block/Zone Display" on page 116
- "Ghost Blocks" on page 118

Interaction Of View And Edit Commands

When on the Edit screen, the View tools can be activated at any time during operation of the drawing tools. Control is returned to the active drawing tool after completing the view process. For example to draw a block perimeter adjacent to an existing cylindrical block:

To continue drawing the perimeter around the other side of the cylindrical block, click on the [Orbit](#) tool and orbit the model to reveal the other side and then use the [Pan](#) tool to centre the model:

You can then resume the drawing process either by pressing the <Esc> key or selecting 'Cancel Pan' from the right-click menu:

View Rotation

Accessible from the [Edit](#), [Visualisation](#), [Daylighting](#) and [CFD](#) screens at all levels

DesignBuilder provides several pre-defined standard view rotations:

You can select one of these standard views from the view rotation drop list:

The default 'Axonometric' setting is designed to provide a good general 3-D view of the various components at each model level.

Alternative ways to access the view rotation commands are:

- For **Axonometric** view, press the A keyboard key.
- For **Plan** view, press the P keyboard key.
- For **Right** view, press the R keyboard key.
- For **Left** view, press the L keyboard key.
- For **Back** view, press the B keyboard key.
- For **Front** view, press the F keyboard key.

Orbit

Accessible from the Edit, [Visualisation](#), [Daylighting](#) and [CFD](#) screens at all levels

The **Orbit** tool is used to rotate the view around the model. To orbit the model click on the **Orbit** tool and then press the left mouse button and keep the button pressed as you move the mouse cursor, the view will orbit around the model.

Alternative ways to access the **Orbit** command are:

- Hold <Shift> key and move mouse while pressing the right mouse button
- Move mouse while pressing the centre mouse button/wheel (if you have one).
- Hold the <Ctrl> + <Shift> + O keys to start the **Orbit** command then hold left mouse button and move mouse.

Tip: It can be helpful to understand how the orbit command works to ensure smooth operation. When the orbiting command is started, DesignBuilder needs to calculate a centre point around which to rotate the view. To do this a ray is fired into the centre of the screen, which should ideally intersect with a part of the model that you want to see. If this is not the case and the ray to the centre of the screen instead finds a far distant point, then the centre of orbit will be that far distant point. The effect of this when you start to move

the mouse to change views can be rather disconcerting as the model will tend not to orbit as expected. **To avoid this sort of problem it is important to ensure that the object being viewed is in centre of the screen and that any holes between the building blocks are not in the centre.** If you do encounter any strange effects with the Orbit command, an easy solution is to select a new view from the [View Rotation](#) drop list in the top right of the screen (e.g. the **Axonometric** option) or to use the [Fit View](#) command.

Note: when using the **Orbit** command after the [Zoom Window](#) command you may see a very rapid and uncontrolled movement. This is usually because of the way that the previous Zoom Window operation was done. That operation works best if the 2 corners selected to create the zoom window area are both on the part of the model you wish to view. If either of the corners selected are outside the model (e.g. on the white background or in distant parts of the model) then the operation can have these unintended effects. This happens because the centre point of the **Orbit** operation is in the far distance.

Zoom Dynamic

Accessible from the Edit, [Visualisation](#), [Daylighting](#) and [CFD](#) screens at all levels

To zoom in and out from the current model point of view, click on the **Zoom** tool, then press the left mouse button and keep the button pressed as you move the mouse cursor, the view will zoom in as you move the mouse cursor down and out as you move it up.

Tip: To centre the view on the current mouse position and start zooming, press the Z key first.

Alternative ways to access the **Zoom dynamic command** are:

- Hold <Ctrl> key and move mouse while pressing the right mouse button.
- Hold <Ctrl> key and move mouse while pressing the centre mouse button (if you have one).
- Hold the <Ctrl> + <Shift> + Z keys to start the **Zoom dynamic** command then hold left mouse button and move mouse.
- As mentioned above press Z to centre the view on the current mouse position and start zooming by pressing left mouse button and moving mouse.

Zoom Window

Accessible from the Edit, [Visualisation](#), [Daylighting](#) and [CFD](#) screens at all levels

The **Zoom Window** tool is used to zoom in on a selected area of your model. To create a window on an area of the model, click on the **Zoom Window** toolbar icon and move the mouse cursor to a corner of the window you want to create, then press the left mouse button and keep the mouse button pressed as you drag the window, when you release the mouse button, the view will zoom to the extents of the defined window.

Alternative ways to access the **Zoom Window** command are:

- <Ctrl> + <Shift> + W keyboard keys.

Note: the **Zoom Window** operation works best if the 2 corners selected to create the zoom window area are both on the part of the model you wish to view. If either of the corners selected are outside the model (e.g. on the white background or in distant parts of the model) then the operation can have unintended effects when applying a subsequent [Orbit](#) command where the centre point of the Orbit operation is in the far distance.

Fit View

Accessible from the Edit, [Visualisation](#), [Daylighting](#) and [CFD](#) screens at all levels

The **Fit view** tool is used to zoom your view to a distance which will enable the whole model to be made visible and centred in the 'Edit' window.

Alternative ways to access the **Fit View** command are:

- Press the w keyboard key.
- <Ctrl> + <Shift> + F keyboard keys.

Pan View

Accessible from the Edit, [Visualisation](#), [Daylighting](#) and [CFD](#) screens at all levels

The **Pan** tool is used to move the model point of view vertically and horizontally across the plane of the screen. To pan the view, click on the **Pan** tool, then press the left mouse button and keep the button pressed as you move the mouse cursor, the point of view will pan horizontally as you move the mouse cursor left and right and vertically as you move it up and down.

Alternative ways to access the **Pan** command are:

- Hold <Shift> + <Ctrl> keys and move mouse while pressing the right mouse button
- Hold <Shift> key and move mouse while pressing the centre mouse button (if you have one).
- Hold the <Ctrl> + <Shift> + N keys to start the **Pan** command then hold left mouse button and move mouse.

Normal View

Accessible from the Edit screen at Surface level

At the [surface level](#), The **Normal** button is displayed at the rightmost end of the toolbar when at surface level and can be used to rotate the current view to be normal to the surface and to automatically zoom in so that the extents of the surface fill the view.

The [Default surface normal view](#) Program option allows you to control whether the normal view is from the outside or the inside.

Walk-Through

Accessible from the [Visualisation](#) and [CFD](#) screens at Building level

When you are at building level, the Walk-through view command allows you to move through the model using the mouse or keyboard to control the direction of movement and of the camera. It provides a useful way to obtain specific views of the model more quickly than is possible using the normal [Orbit](#), [Zoom](#), [Pan](#) etc tools. For example to look more closely at a particular area of a CFD results slice or to gain a specific interior view when analysing shading on the Visualisation screen.

Tip: One key feature of the Walk-through command is that the z (height) position of the camera is maintained constant. This helps to give the impression of walking through the model. To change floors, or to otherwise change the z-position, it can be convenient to use the [Pan](#) command. You can gain quick access to the Pan command without stopping the Walk-through by holding the <Shift> key and the middle mouse button/wheel down while moving the mouse.

When Using The Mouse

While holding the mouse left button down, move the mouse around the screen in the direction you wish to move. Move the mouse cursor up the screen to move forwards and down the screen to move backwards. Likewise, to turn left move the mouse to the left of the screen, and to turn right move the mouse to the right of the screen. You can combine forward/backward movement and left/right direction changes by moving the mouse diagonally towards the appropriate corner.

Other tools often used together with the Walk-through tool are [Look around](#) or [Orbit](#) (to change the camera direction), and [Pan](#) to move vertically up and down, which is not possible with the Walk-through command.

Tip: You can move more quickly by holding the <Shift> key down while using the above mouse commands.

When Using Keys

The Walk-through tool is most responsive when using the mouse, but it is also possible to access it using the keyboard as follows.

Use the <Up> and <Down> keys to move forwards or backwards in the current direction.

Use the <Left> and <Right> keys to change direction.

Tip: The best way to learn how to use the Walk-through tool is to try it for yourself!

Look Around

Accessible from the [Visualisation](#), [Daylighting](#) and [CFD](#) screens at Building level

When you are at building level, the Look Around view command allows you to change the direction of camera view using the mouse . It allows you to obtain specific views of the model more quickly than is possible using the normal [Orbit](#), [Zoom](#), [Pan](#) etc tools. For example to look more closely at a particular area of a CFD results slice or to gain a specific interior view when analysing shading on the Visualisation screen.

When Using The Mouse

While holding the mouse left button down, move the mouse around the screen in the direction you wish to view. Move the mouse cursor up the screen to look up and down the screen to look down. Likewise, to look left move the mouse to the left of the screen, and to look right move the mouse to the right of the screen. You can combine forward/backward/left/right view changes by moving the mouse diagonally towards the appropriate corner.

Other tools often used together with the Look Around tool are "Walk-Through" on page 115 and [Orbit](#) (to change the camera direction), and [Pan](#) to move vertically up and down, which is not possible with the Walk-through command.

Surrounding Block/Zone Display

Accessible from the Edit Screen at Block and Zone Levels

It is sometimes useful to be able to gain a quick visual indication of the location of the current block or zone in the context of the rest of the building or block. The **Surrounding block/zone display** toolbar and menu command provides a convenient way to control:

- a. the visibility of other blocks in the current building (when working at block level) and,
- b. the visibility of other zones in the current block (when working at zone level).

Note: The same functionality can also be accessed from the [Surrounding block display](#) and the [Surrounding block zone display](#) options on the Display tab of the Model options dialog, however, it is usually easier to use the toolbar icon. Note that the Model options dialog provides additional functionality in that it also allows a zone to be seen in the context of all the other zones in the building if required. This less commonly required option is not available from the toolbar which only allows zones to be seen in the context of the rest of the current block.

Example use of the Surrounding block/zone display command at zone level

Example use of the **Surrounding block/zone display** command at block level

Ghost Blocks

Accessible from the Edit Screen at Building Level

There may be times when it is helpful to be able to ghost one or more blocks in the model so that they become semi-transparent, allowing blocks behind them to be accessed and selected for editing. The **Ghost selected blocks** and **Show all blocks** toolbar icons described here provide the most convenient way to control the ghosting of blocks in the model.

The Ghost blocks mechanism applies to both building blocks and component blocks.

An alternative (slower) method of controlling building block ghosting is to use the [Active](#) checkbox on the Blocks tab of the Model options dialog.

Ghost Selected Blocks

Accessed from Edit Screen, Building Level

This tool is available on the Edit screen at building level when one or more blocks are currently selected.

To ghost one or more blocks:

- Go to building level and select the building and/or component blocks to be ghosted.
- Click on the **Ghost selected blocks** toolbar icon.

Ghost selected blocks example

Note: Once in a ghosted state, blocks cannot be selected. There are 2 ways to "un-ghost" them:

- Navigate to building level and use the **Show all blocks** command (below).
- Navigate to the block to be un-ghosted, open the Model Options dialog and on the Block tab, check/uncheck the [Active](#) checkbox. This allows the ghosting of blocks to be controlled independently and can be useful for un-ghosting just one block at a time.

Show All Blocks

Accessed from Edit Screen, Building Level

This tool is available on the Edit screen at building level when one or more blocks are currently ghosted. To display or "unghost" all blocks in the building:

- Go to building level.
- Click on the **Show all blocks** toolbar icon

Perimeter Drawing Options

Blocks, courtyards and surface openings are all created using perimeters. When any of these element drawing tools are activated, perimeter options can be accessed from the 'Drawing Options' data panel, for example when the [Draw window](#) tool is active at the surface level:

See also the [Blocks and dimensioning protocols](#), [Adding blocks and using the measure tool](#), [Add surface, increment snaps](#), [Drawing arcs, circles and domes](#) Tutorials

Shape

Three perimeter shapes are provided to enable specific perimeter topologies for blocks and surface openings to be drawn efficiently:

- **1-Polygon**
- **2-Rectangle**
- **3-Circle**

Polygon

The **1-Polygon** is generally the most useful shape and can be used to draw block and opening perimeters of any topology. The **1-Polygon** shape also allows you to change the line type from a straight line to an arc. To draw a perimeter using the **1-Polygon** shape, start drawing the first line by clicking anywhere in the active drawing plane to place the starting point, then move the mouse cursor and click to place the line end-point, you can use the [snaps and the protractor](#) to help with alignment. Continue placing perimeter lines in the same way. If at any time you want to cancel the last line that you placed, you can press the ESC key or select the **Undo last point** option from the right-click menu. If you want to incorporate an arc within the perimeter, you can change the [line type](#) to **2-Arc** and then place the centre-point of the arc:

To complete the perimeter, move the mouse cursor to the beginning of the first perimeter line, which activates the [end-point](#) snap and click on it to connect the lines:

Rectangle

The **2-Rectangle** shape allows you to draw perimeters by placing diagonally opposite corners of a rectangle:

Circle

The **3-Circle** shape is used to draw circular perimeters by placing the circle centre and then setting the radius by placing a second point:

The associated **Segments** option allows you to control the accuracy of the circle. In DesignBuilder geometry, circles are actually composed of polygons and the accuracy of the representation can be controlled by defining the number of segments (or lines) used in generating the polygon. Generally speaking, the greater the number of segments used will result in more memory usage and processing time and so, particularly in the case of blocks, it's advisable to use the default number of segments where possible.

More information on using the Circle shape can be found in the [Drawing arcs, circles and domes](#) tutorial.

Line Type

When the perimeter [shape](#) is set to **1-Polygon**, you can set the perimeter **Line type** to one of:

- **1-Straight line** or
- **2-Arc**

Straight Line

When the line type is set to **1-Straight line**, a perimeter is drawn by placing the origin and then a series of line end-points:

Arc

To incorporate an arc within a perimeter, set the line type to **2-Arc**. An arc is defined using the sweep angle and number of segments:

A negative sweep angle can be used to create an arc in an anti-clockwise direction. In DesignBuilder geometry, arcs are created using a number of segments or straight lines and the accuracy of the representation can be controlled by defining the number of segments. Generally speaking, the greater the number of segments used will result in more memory usage and processing time and so, particularly in the case of blocks, it's advisable to use the default number of segments where possible.

To draw the arc, place the arc centre:

More information on using the Arc line type can be found in the [Drawing arcs, circles and domes](#) tutorial.

Snaps, Drawing Guides, Protractor And Grids

A number of drawing aids are provided to enable block perimeter lines, partitions, etc. to be drawn precisely:

- [Direction Snaps](#)
- [Point Snaps](#)
- [Drawing Guides](#)
- "Protractor tool" on page 141
- "Drawing Grid" on page 143

These tools are made available in the Drawing Options panel in the bottom left of the screen when the drawing tools are activated.:

Direction Snaps

When drawing perimeter lines, block partitions or surface openings direction snaps can be used to draw lines:

- [Parallel with the active drawing plane axes \(Axis snap\)](#),
- [Parallel with existing elements \(Parallel snap\)](#) or
- [Perpendicular to existing elements \(Normal snap\)](#).

See also the [Adding blocks and using the measure tool](#) Tutorial

Axis Snap

The axis snap check boxes are displayed under 'Direction snaps' in the 'Drawing Options' data panel when the various drawing commands are active. The axis snap is used to draw lines parallel with the major axes of the active drawing plane.

As you move the cursor around to draw a line, the line will change colour and 'stick' slightly as it becomes parallel with one of the major axes:

You can use axis snap to draw block perimeters on planes of any orientation. If the plane is non-horizontal, the axis snap applies to the local coordinate system of the plane as if it were rotated to the horizontal:

If the axis snap is operating on a horizontal plane, the perimeter line will change colour to red if the line is snapped to the X-axis or green if it's snapped to the Y-axis. However if the active drawing plane is not horizontal, the line will change colour to orange for the X-axis and purple for the Y-axis.

At the building level, when the active drawing plane is horizontal, you can also snap block perimeters and [construction lines](#) to the Z-axis:

which allows you to draw horizontally extruded blocks, this process is explained under [Adding Blocks](#)

See also the [Blocks and dimensioning protocols](#) tutorial.

Parallel Snap

The parallel snap is used to draw lines parallel with the edges of existing objects. The parallel snap check box is displayed under 'Direction snaps' in the 'Drawing Options' data panel when the various drawing commands are active. To draw a block perimeter line to be parallel with an existing block edge, switch the parallel snap on and move the mouse cursor to touch the edge with which the current perimeter line is to be parallel:

This will enable the active perimeter line to infer a direction from the selected edge and you can lock this inference by pressing the SHIFT key to prevent a parallel inference being picked up from an unwanted edge. So press the SHIFT key and move the mouse cursor to a position approximately parallel with the edge, the cursor will 'stick' when the parallel snap operates and the perimeter line will change colour to cyan:

When the parallel snap is in operation, intersections are automatically calculated with [drawing guides](#) to allow the two to be combined, so you can snap to the intersection of the two.

Normal (Perpendicular) Snap

The normal snap is used to draw lines perpendicular to the edges of existing objects. The normal snap check box is displayed under 'Direction snaps' in the 'Drawing Options' data panel when the various drawing commands are active. When the normal snap is switched on and you draw a line string, each line will automatically snap to be perpendicular with its predecessor if it exists:

To draw a block perimeter line to be perpendicular with the edge of an existing block, move the mouse cursor to touch the edge and then move it to be approximately perpendicular to it, the cursor will automatically snap to a line which is exactly perpendicular.

You can lock the perpendicular snap by pressing the SHIFT key which will prevent the cursor from picking up an unwanted direction inference. In this case, a [construction line](#) has been placed [parallel](#) with the block edge to help in positioning the new block. The perimeter line locks to a perpendicular from the construction line:

When the normal snap is in operation, intersections are automatically calculated with [drawing guides](#), allowing you to snap to the intersection:

Offset Snap

The offset snap is used to draw [partitions](#) and [voids](#) parallel to existing walls and partitions at a fixed offset distance. This help topic describes the use of offset snap for drawing partitions, but the information is equally applicable to drawing voids at a fixed offset from the perimeter.

The offset snap check box is displayed under [Direction snaps](#) in the **Drawing Options** data panel when the [Draw partitions](#) command is active.

The offset snap can be used whenever a string of partitions is to be located at a fixed offset from a perimeter, but can be specifically applied to dividing large open plan spaces up into 'perimeter' and 'core' zones for thermal simulation.

When the offset snap is switched on, an additional **Distance** item will be displayed under the offset snap check box in the Drawing options panel which allows you to define the offset distance. When you first switch on the offset snap, having clicked on the [Draw partition](#) icon, you will see offset snap indicators displayed as you move the cursor within the snap range of an existing wall or partition:

The offset snap works in conjunction with the other snaps and so, for example, you can start an offset partition at a fixed distance from the beginning of an existing wall using the [edge snap](#) in combination with the [increment snap](#):

After placing the beginning of the partition, the 'rubber-banded' partition will be automatically snapped to the offset from the selected wall and as you move the cursor to the next connected wall segment, the offset snap indicator will appear again:

As you move the cursor, you will see that the offset snap interacts with other snaps allowing you to position partitions accurately. If you find that the other snaps are interfering with the offset snap, you can switch them off by pressing the SHIFT key.

Completed perimeter:

Note: The offset snap command prevents access to the normal end-point, mid-point and edge snaps. You must switch off offset snap to re-enable these.

Note: If you override the offset snap (by snapping to a drawing guide or edge), the offset snap has to be discontinued until the command (partition or void) is re-started.

Point Snaps

When the various point snaps are switched on, a coloured indicator is displayed when the mouse cursor is close to a key-point on an existing element allowing a perimeter or partition line end-point to be positioned precisely at the selected key-point.

See also the [Blocks and dimensioning protocols](#) and [Adding blocks and using the measure tool](#) tutorials.

The following point snaps are available:

- [End-point snap](#)
- [mid-point snap](#)
- [Edge snap](#)
- [DXF snap](#)
- [Snap To Lower Perimeters](#)
- [Increment snap](#)

Note: In some cases Snaps can interfere with attempts to draw to a particular point and in this case you can temporarily switch off the appropriate snap(s) using the check boxes in the Drawing options panel in the bottom left of the screen.

End-point Snap

This snap allows you to snap lines to the end-point of an existing edge. A green indicator is displayed when the mouse cursor is within the snap range of an end-point:

For example, to snap the starting point of a new block perimeter to the end-point of an existing block edge, move the mouse cursor onto the background and press SHIFT to lock the drawing plane to the ground plane. Keep the SHIFT key pressed and move the mouse cursor close to the required edge marker to activate the end-point snap:

Similarly to snap the starting point of a new block partition to the end-point of an existing partition, make sure that the 'End-point' snap is switched on and move the mouse cursor close to the partition end-point to activate the snap:

See also the [Adding blocks and using the measure tool](#) tutorial.

Mid-point Snap

For details of using the 'Mid-point' snap, please refer to the [End-point](#) snap.

See also the [Adding blocks and using the measure tool](#) tutorial.

Edge Snap

The edge snap allows you to snap to any point on the edge of an existing object. The edge snap can be used in conjunction with the increment snap to enable a point to be located along an edge by moving it in defined increments. A red indicator is displayed when the mouse cursor is within the snap range of an edge and distance indicators are also displayed to help in locating a point a specific distance from either end of the edge:

By switching the increment snap on, the point can be moved along the edge in defined increments. For example, if you wanted to start a block perimeter line at 6.0 metres from the end of the block, after switching on the increment snap, you could set the snap increment to say 0.5m and then move the mouse cursor to the edge at a distance of 6.0 metres from the end-point:

If you wanted to locate the beginning of the perimeter line at a specific distance from the other end of the edge, you can switch the end of the edge from which the increment snap operates by toggling the 'Switch snap increment direction' switch:

See also the [Adding blocks and using the measure tool](#) tutorial.

DXF Snap

The DXF snap only applies when [DXF data](#) has been imported from an external file. The DXF snap enables you to snap to the end-points of DXF lines:

Note: You should generally switch DXF snap off when drawing partitions at block level and simply use the DXF lines as a visual guide. This ensures that partitions correctly snap to perimeters instead of snapping to DXF lines which may be very close to the perimeter but not actually touching.

See also the [Importing drawing files](#) tutorial

Snap To Lower Perimeters

This snap allows you to snap to adjacent lower block perimeters and partitions. This snap is switched on by default but it can be useful sometimes to switch it off to avoid snapping to partitions in the block below.

When this snap is active, lines are also displayed at block level to represent any partitions and block perimeters from the block(s) below. Sometimes these lines can cause confusion, especially if a 2-D drawing has been loaded as well, and in this case it may help to switch the **Snap to lower perimeters** option off.

Increment Snap

The increment snap applies to any process that involves moving a point or a surface in a particular direction. Such processes include drawing block partitions or perimeter lines which have an active [direction snap](#) or dragging the surface of a block normal to the original surface position. The increment snap allows you to move a point in a particular direction by defined increments. You can think of the increment snap acting in the same way as a conventional CAD drawing grid and in fact if you were just to use the axis snaps it would have the same effect, however the increment snap is more powerful in that it provides this type of incremental snap along any defined vector not just the axis vectors.

See also the [Add surface, increment snaps](#) tutorial

The increment snap may be particularly useful during early stage design when you want to place geometry with reasonable accuracy but don't want to be constantly keying-in distances.

Note: the increment snap will only come into operation when you are drawing a line or moving a surface along a defined vector. For example if you are drawing a block perimeter parallel with an existing block edge, the increment snap will operate when the parallel snap is active and in this case you would be able to move the mouse cursor along the parallel vector in increments of 0.5m:

Increment snap operates when any of the direction snaps are active

The increment snap also works in conjunction with the [Protractor](#):

Increment snap operates when line snapped to protractor angle

You can use the increment snap to control the location of block faces when you extrude a block on creation or drag faces during an [edit](#) or [stretch](#) operation:

The increment snap also comes into operation when an edge snap is active, allowing you to snap to the edge by increments from either end, please see [edge snap](#) for details.

Switch snap increment direction

Increment snap provides increments between the 2 end points of the reference line and increments can only be generated from one end point at a time. You can reverse the direction so that increments are generated from the other end of the reference line by checking the **Switch snap increment direction** drawing option. This option is found immediately below the Increment snap option (screenshot above).

Drawing Guides

Drawing guides are invisible lines that are automatically generated as soon as a drawing plane becomes active during a drawing operation. Drawing guides are parallel with the active drawing plane X and Y axes and run through all end-points and mid-points of existing object edges, which lie in the same plane as the drawing plane. As you move the cursor in the vicinity of a drawing guide, it will become visible and you can then snap the cursor to any point on the guide. When drawing guides are used in conjunction with [Direction Snaps](#) or the [Protractor](#) they offer a powerful mechanism for locating perimeter lines in relation to existing object edges.

See also the [Adding blocks and using the measure tool](#) tutorial

For example to create a triangular window in a surface with the same height as an existing opening, first click on the [Draw window](#) tool and check that the perimeter shape is set to 'Polygon', switch the protractor on and then move the cursor to align approximately with the lower edge of the existing window which will automatically snap the cursor to the required drawing guide:

Click to place the window origin and move the cursor to snap to the drawing guide associated with the existing window upper edge, the protractor angle lock will automatically combine with the drawing guide:

Click to place the apex of the window and then place the next point in a similar fashion:

Completing the window perimeter:

Note: In some cases Drawing guides can interfere with attempts to draw to a particular point and in this case you can temporarily switch off Drawing guides using the check boxes in the Drawing Options panel in the bottom left of the screen.

Protractor Tool

The protractor tool is used to draw perimeter lines and partitions at specified angles in relation to the current drawing plane. The protractor can be activated from the 'Drawing options' data panel, which is displayed when any of the drawing tools are used. For example, to create an offshoot projecting from an existing block with a roof slope of 30°, move the cursor over the existing block surface, press the SHIFT key to lock the drawing plane and draw the first perimeter line, snapping to the base edge using [end-point snap](#):

Draw the second perimeter line to connect to the mid-point of the block edge and then activate the protractor:

The protractor will automatically snap to the current drawing plane and as you move the mouse cursor, the perimeter line will snap to the protractor in angular increments, which can be set in the 'Drawing options' data panel. The rotation angle is displayed at the centre of the protractor. Move the cursor until the displayed angle is 30° and then move the snapped line towards the upper block edge. When the line end-point nears the edge, it will 'stick' to the edge and the [edge snap](#) marker will be displayed:

Click to accept the point and complete the perimeter by snapping to the block face vertices using the [end-point](#) snap:

Drag the perimeter to complete the offshoot:

See also the [Cutting blocks, protractor tool](#) Tutorial

Drawing Grid

The **Drawing Grid** Drawing option provides a different, more visual way to obtain snap points based on a grid when drawing new objects at Block and Surface levels:

- **Block** when using any block level drawing tool ([Partitions](#), assembly, [Construction lines](#))
- **Surface** when using any surface level drawing tool ([Window](#), [Subsurface](#), [Hole](#), [Door](#), [Vent](#), [Boundary conditions](#), [Construction lines](#)).

The Drawing Grid can be accessed when at block or surface level from the bottom left **Drawing Options** panel when adding a new object. See the screenshot below which shows the Grid in use at block level.

The Grid can be used in combination with [Increment snap](#) and the other [Point Snap](#) options.

Note: Once the **Drawing Grid** option has been selected on the **Drawing Options** panel, the actual display of the grid only becomes active when a drawing tool has been selected (e.g. [Draw Window](#) at the surface level).

Set drawing grid origin

When the **Drawing grid** display is active, an additional **Set drawing grid origin** tool becomes available on the main Toolbar: 

This tool enables the drawing grid to be dimensioned from any key point in the display. For example, at the surface level, the corner of an existing window could be used to set the grid origin and then additional openings could be added relative to that existing window.

See also: "Increment Snap" on page 137

Construction Lines

Construction lines can be used to help in the creation of precise geometry. You can [draw construction lines](#) using the [snaps and the protractor](#) to lie at defined locations and then use these lines as a framework from which or to which various object geometries can be projected or attached.

At the building level, construction lines can also be snapped to the Z-axis to form vertical planes from which block geometry can be extruded.

Construction line snap points can be picked up at all levels regardless of the level at which they were drawn. For example all of these operations are possible:

- Draw construction lines at building level and pick up snap points for these at surface level for accurate drawing of openings etc.
- Draw construction lines at block level and access them at zone and surface levels for positioning openings, lighting sensors, CFD fans and assemblies.
- Draw construction lines at surface level to indicate the position of a shading device relative to windows and use snap points to draw and position a component block at building level.

Note: Because Construction lines are not part of the model (in the same way that [outline blocks](#) are not part of the model) they do not appear in the Navigator panel.

See also:

- "Drawing Construction Lines" on page 145
- "Removing Construction Lines" on page 149

More information on how to work with construction lines can be found in the [Shading using standard component blocks](#) and [Adding a roof, construction lines](#) tutorials.

Drawing Construction Lines

Construction lines are drawn in the form of line streams. To draw a construction line, click on the **Place construction line** tool and start drawing the first line by clicking anywhere in the active drawing plane then move the mouse cursor and click to place the line end-point, you can use [point](#) snaps, [direction](#) snaps, [drawing guides](#) and the [protractor](#) to help with alignment. Continue placing construction lines in this way. If at any time you want to cancel the last line that you placed, you can press the <Esc> key or select **Undo last point** from the right-click menu.

Note: Although each construction line is a 1-D object, when placing a stream of construction lines DesignBuilder considers the lines to lie on a single drawing plane. Once you have defined three points in the line stream, that defines the drawing plane and all subsequent points will be located in that plane. The line stream can be ended at any time by pressing the <Enter> key and then the next segment can be positioned on any other plane.

Construction lines have numerous applications in forming temporary attachment points during the creation of precise geometry. As a simple example, if you want to place a block at a precise distance from the angled wall of an existing block, you could switch the [Normal](#) snap on, click on the **Place construction line** tool and draw a perpendicular line a precise distance from the wall. To draw the perpendicular line, place the first point at an end-point of the wall baseline, move the mouse cursor to touch the baseline and press <Shift> to lock the direction inference, then move the mouse cursor to activate the perpendicular lock and key-in the required distance:

You could then place a second construction line normal to the first line and key-in the required length:

You can then snap to the construction line to draw the new block perimeter:

The finished block:

You can also snap to the intersection of construction lines:

At the building level, construction lines can be snapped to the Z-axis in order to create vertical planes to which block geometry can be attached. To draw construction lines in a vertical plane, switch the Z-axis snap on, click on the 'Place construction line' tool and place the first point on the ground plane or any other horizontal plane. Move the mouse cursor to snap the current line to the Z-axis:

You can then use the protractor to place the next line in order to accurately define a plane:

After placing the second line, the two construction lines form a vertical plane that can be used for extruding blocks or as a plane to be used as a cutting plane.

Note: Constructions lines can be copied, rotated, scaled etc like any other object.

Note: When drawing construction lines at **block level** it is possible to get a fuller range of snaps by selecting the **2-Zone inner surfaces** Snap mode.

See also the [Adding a roof, construction lines](#) tutorial

Tip: Construction line streams are used as a part of the process when using the [Follow Path](#) tool.

Removing Construction Lines

You can remove construction lines by [selecting](#) and [deleting](#) them individually, or you can remove all construction lines from the model by selecting the **Remove all construction lines** command from the [Edit](#) menu.

See also the [Adding a roof, construction lines](#) tutorial

General Operations

This section describes general geometric operations:

- [Select](#)
- [Move](#)
- [Clone \(copy\)](#)
- "Mirror" on page 155
- [Rotate](#)
- [Stretch](#)

- [Delete](#)
- "Measure" on page 161

Select

The **Select** tool acts like pressing the <Esc> key to cancel another command and enable graphical selection of model objects.

Selecting a single object

To select an object, click on the **Select** tool, or press <Esc>, or select **Select** from the right-click context menu, then move the mouse cursor to the object to be selected and click with the mouse to select it. The colour of the object temporarily changes to light red to indicate that it is selected.

Selecting multiple objects

To select multiple objects, use one of the following methods:

- Press and hold the <Ctrl> key while clicking on objects, or,
- Drag a selection rectangle (aka "rubber band") by pressing and holding the left mouse button and dragging a window across the required selection area. When you release the mouse button, all the objects that are entirely within the selection window will be selected. Any objects that are only partially within the selection rectangle will not be selected. This is often the preferred selection method when many objects need to be selected as it doesn't require each item to be clicked on individually.

The screenshots below illustrate the process.

Dragging a selection rectangle around all blocks in a model

On releasing the mouse key, the objects are selected.

Tip: If you need to select most objects within an area, but not all of them, you can use the selection rectangle tool to select all objects and then deselect the objects that do not need to be selected by holding the <Ctrl> key and clicking on them.

Note: When using the selection rectangle please be aware that any openings in the selection rectangle that are hidden by model surfaces will also be selected. It is therefore important to carefully check which openings have been selected when using the select command before carrying out a significant operation on the selection set, such as deletion.

See also the [Selecting, moving, cloning and deleting objects](#) tutorial.

Move

You can use the **Move** command to move blocks, partitions, courtyards and openings. You can also use Move to [set the position of daylight sensors](#). To move an object, first select it and then click on the **Move** tool or select 'Move' from the right-click context menu. If you want, you can move several objects at the same time by

doing a [multiple selection](#). You then need to define a 'handle point' for the move operation, the handle point can be any point on a model surface or ground plane but more usually will be a vertex on the object that you want to move, so make sure that the end-point snap is switched on, move the mouse cursor to the required object vertex and snap to it:

When you release the mouse button, you will be able to move the object to any required location. As you move the object, a displacement line is displayed to show how far the object has been moved, the displacement line can be snapped to the [axes](#) or the [Protractor](#). When a [direction snap](#) is active the [increment snap](#) can also be used:

You can then click the mouse button to place the object.

At the building level, blocks can be moved in three dimensions onto any existing block face in the model. As you move the block around the model, each block face will highlight in blue as the block handle point is moved across it, indicating that the face has become the active drawing plane.

You can lock the active drawing plane by pressing the <Shift> key to position the block:

See also the [Selecting, moving, cloning and deleting objects](#) tutorial.

Clone (Copy)

For details of using the **Clone** tool, please refer to the [Move](#) tool. The process is identical except that when cloning, the original block is retained.

See also the [Selecting, moving, cloning and deleting objects](#) tutorial.

Mirror

Mirrored copies of blocks, partitions, courtyards and openings can be created through the **Mirror** command. Objects can be mirrored in either the x or y axis. The process involved in using the mirror command is described below.

Mirror Block

To use the Mirror command to create a mirrored copy of a building block:

1. Go to building level (or block level if you wish to mirror a block-level component block or assembly).
2. Select the block to be mirrored.
3. Click on the **Mirror** toolbar icon.
4. In the Drawing Options panel select the Reflection axis. Choose from x or y-axis as the mirror plane.

5. Select the reference point on the existing block. You should choose a point whose corresponding mirrored point can be used to accurately snap the new mirrored copy in place.

6. Once you have selected the reference point the mirrored copy is created and can be positioned as required, usually by snapping the mirrored reference point to the required place.

Mirror Openings

A similar process is used to create mirrored copies of a selected set of openings either at building or surface level. The instructions below are for working at surface level, but the process is the same when working at building level.

1. Go to the surface containing the openings to be copied and mirrored.
2. Select the openings.
3. Click on the **Mirror** toolbar icon.
4. In the Drawing Options panel select the Reflection axis. Choose from x or y-axis as the mirror plane.

For surfaces, choosing to mirror in the x-axis means to mirror in a line in the horizontal direction and the y-axis means that the mirror line is in the vertical direction.

5. Select the reference point on the existing set of selected openings by clicking with the mouse. It is usually convenient to choose an end point snap point whose corresponding mirrored point can be used to accurately snap the new mirrored copy in place.

6. Once you have selected the reference point the mirrored copy is created and can be positioned as required, usually by snapping the mirrored reference point to the required place. You can key in an exact distance to move the reference point while creating the mirrored copy.

7. Once the mirrored copy is in place, click with the mouse to actually create the new opening(s).

Mirror Partitions And Courtyards

The process of mirroring partitions and courtyards is carried out at block level and is similar to the processes described above for blocks and openings.

Rotate

You can rotate blocks, partitions, courtyards and openings. To rotate an object, first select it and then click on the 'Rotate' tool or select 'Rotate' from the right-click menu. If you want, you can rotate several objects at the same time by doing a [multiple selection](#). As you move the cursor back into the Edit screen, the Protractor will be displayed at the cursor position. At the building level, you can rotate a block around an axis point defined on any plane and as you move the cursor from surface to surface in the model, each surface will highlight in blue to show that it's the active drawing plane and the protractor will automatically rotate into the same plane:

You define the rotation axis about which the object will be rotated by clicking the mouse when the mouse cursor is in the required location, you can use the various [snaps](#) and [drawing guides](#) to locate the axis point. After placing the axis point, you can then rotate the object around the axis:

In the case of partitions and courtyards at the block level, the active drawing plane for rotation is always the plane of the block floor and in the case of surface openings, the active drawing plane is always the surface plane:

See also the [Stretch, drag face and rotate tools](#) tutorial.

Stretch

Building, component and outline blocks can be stretched (scaled) when at the building level. To stretch a block, go to building level then select it and click on the **Stretch** toolbar icon, or select 'Stretch' from the right-click menu. When you activate the Stretch tool, a wire frame is displayed around the extent of the block and as you move the cursor across the faces of this frame, each face will highlight in the colour of the axis to which the face is normal:

If you then click on one of these highlighted faces, you can then stretch the block along the axis normal to the face. If the increment snap is switched on, the block can be stretched in increments:

In the case of the Z-axis, the stretch operation will only operate along the positive Z-axis:

Tip: By default the stretch will take place in the direction defined by the face that you select. However to stretch in both directions equally, hold the <Shift> key down while dragging.

Tip: You can also key in the *new dimension* using the keyboard. Note the difference to the [Drag face](#) tool where the *increment* in the extrusion is keyed in.

Note: You can only stretch one block at a time.

See also the [Stretch, drag face and rotate tools](#) tutorial.

Delete

To delete an object, first select the object you want to delete and then click on the **Delete** tool or select 'Delete' from the right-click menu. If you want, you can delete several objects at the same time through [multiple selection](#).

Tip: It is usually quicker to simply press the <Delete> key on the keyboard.

See also the [Selecting, moving, cloning and deleting objects](#) tutorial.

Measure

The measure tool allows you measure distance, angles and areas *on single planes* in the model. To use the tool, navigate to the part of the model you wish to measure, click on the Measure toolbar icon, select the type of measurement to be made in the Display options panel on the left of the screen. The options are:

- **1-Distance** - Click twice on a plane to define the length between the 2 points.
- **2-Angle** - Click three times on a plane to define the area between the 2 lines.
- **3-Distance** - Draw an enclosed polygon by clicking with the mouse on a single plane.
- **4-Perimeter** - Draw an enclosed polygon by clicking with the mouse on a single plane.

The requested data is displayed highlighted in the Drawing Options panel.

Note: When measuring at block level it is possible to get a fuller range of snaps by selecting the **2-Zone inner surfaces** Snap mode.

See also the [Adding blocks and using the measure tool](#) tutorial.

Importing Geometric Data

There are 2 ways to import geometric data into DesignBuilder:

- [Importing floor plans](#) where 2-D floor plan data is imported either from CAD or scanned paper drawings.
- [Import 3-D BIM](#) data using the gbXML data format.

See also:

- "Merge Model Data from File" on page 181 to import the attribute settings, components and templates, HVAC system, assemblies and component blocks from a previously created DesignBuilder model into a newly imported BIM model.

More information on Importing model geometry can be found in the [Importing drawing files](#) tutorial

Import 2-D Drawing

DXF and other bitmap-type drawing data formats can be imported in the form of 2-D floor plan or elevation layout drawings. These can be used to trace block perimeters, partitions and façades as a fast way to enter the model geometry. A typical process is as follows:

1. Create new dsb site file, select location etc.
2. Import floor plan data (described below).
3. Go to block level and draw partitions by tracing over the drawing data.
4. Import other DXF floor plans for other stories if necessary.

The process of importing elevation drawings for drawing opening often takes place after the main block geometry definition and partitioning has been completed as follows:

1. Import elevation DXF data to the ground plane (you cannot import 2-D drawing data directly to any other plane).
2. Move the DXF object to a wall surface by selecting it and using the [Move](#) command.
3. Go to surface level and trace windows, doors and any other openings by snapping to the DXF data.

It is also possible to use elevation drawings to create the original block form as described below.

Note: It is necessary to switch on the [Show imported 2-D drawing at zone and surface levels](#) Display model option on when using an imported elevation to show the position of windows, doors etc at surface level.

Tip: When a 2-D drawing is loaded, sometimes the drawing data can come between the mouse cursor and objects to be accessed. In this case, pressing the <Shift> key while left mouse clicking allows the drawing to become "transparent" to any clicks, making it easier to access model objects such as blocks and openings, which are behind the drawing data.

Using an Elevation Drawing to Create a Block with Openings

Elevation drawings can also be used for creating horizontally extruded blocks of complex section such as the aircraft hanger elevation drawing below, placed on an outline block ready to create a horizontally extruded block shape.

Using the [Add surface](#) tool, trace the outline of the hanger external façade:

The Cutting tool can be used to remove the original rectangular part of the outline block. The image below shows the outline block from the other side with the rectangular part of the outline block removed so we can see the drawing coplanar with the block facade:

The hanger outline block has now been converted to a building block and once navigated to surface level we are ready to use the drawing to help trace the windows and doors onto the surface:

Note: Make sure that the correct surface is selected when navigating to surface level

Completed hanger block with windows and doors drawn at building level:

More information on Importing floor plans can be found in the [Importing drawing files](#) tutorial

Import Drawing File Wizard

You can import 2-D DXF floor plan files created in AutoCAD or other CAD programs or the other bitmap-based drawing formats listed below. To start the process click on the **Files > Import > Import 2-D drawing file** menu command. This starts a the Import Drawing File Wizard.

With the import wizard open, select the File type to import. You can select from:

- **1-DXF** - 2-D CAD data. This option allows you to snap to the end-points of the DXF line segments, the other bitmap-based formats below do not allow snapping.
- **2-PDF** - PDF drawing file (single page). **Note only PDF files with a single page will import successfully into DesignBuilder.**
- **3-BMP** - Bitmap drawing file.
- **4-JPG** - JPEG drawing file.
- **6-GIF** - GIF drawing file.
- **7-TIFF** - TIFF drawing file.

When you have selected the file type then select the file by clicking into the 'Filename' control. Click on the ellipsis button to open the file browser dialogue box.

Import Drawing File

Units: 1-Metres

Attach at height (m): 0.000

Cancel Help Back Next Finish

Once the floor plan has been imported you can add blocks by tracing over the [external perimeter](#) corners of the floor plan.

DXF File Types

While on the Import drawing file wizard, if you selected a DXF file you must then select the units used in the DXF file from the **Units** drop list. You should be able to find this out from the creator of the CAD model - you are likely to get 'out of range' errors if you get it wrong. For example the CAD drawing may have been defined in millimetres and if you have selected metres as the units, when DesignBuilder tries to read the floor plan everything is 1000x too big and meters become kilometres! The DesignBuilder modeller has a range of several hundred metres and if any data falls outside this, the 'out of range' error occurs.

DesignBuilder supports ASCII DXF, and not binary DXF format. You can convert binary files to ASCII using a utility such as [DDS-CAD Viewer](#).

Tip: DesignBuilder is not able to import DXF files that are already open in other applications, so if you have been checking the DXF file that you plan to import in AutoCAD or other CAD tool, you should make sure to close the file before attempting to import it into DesignBuilder.

You must also set the attachment height at which the 2-D DXF floor plan will be attached in the DesignBuilder model. The DXF data can be moved around the model once it is imported, so you do not need to know the exact attachment height at this stage - you can import the DXF data at zero height and move it to the correct location using the [Move](#) command. Click on the 'Next' button to set up layer visibility:

You can use these controls to switch off unnecessary layers in the DXF data. As you check/uncheck the checkboxes you will see the effect of the change in the Edit view under the Wizard. Click on the 'Finish' button to import the data:

At the **building level**, you can [select](#), [move](#) and [delete](#) DXF data. When you select DXF data, you may need to zoom in to make the selection. You can move DXF file in 3-D and snap the data to the edges of blocks or end-points of [construction lines](#):

Move the DXF data on top of the existing block and snap to an edge end-point:

When you have imported the DXF data you can use the Measure tool to check that the dimensions are correct.

Import DXF floor plans for other stories if necessary. Note that only one set of DXF data can be imported at a time. Once the CAD data has been imported into the model, the source DXF file is no longer needed by DesignBuilder and can be moved or deleted.

Editing DXF Data

Once the DXF data has been imported to the model, it must be selected to allow these operations:

- [Move](#) - move the DXF data
- [Delete](#) - delete the DXF data (not the source file itself).

Also the **Set X-axis for imported DXF** and **Scale DXF drawing** menu commands are available from the **Edit menu** when DXF data is loaded.

Set X-axis for imported DXF

When the command is started click twice to define the end points of a line in the direction of the X-axis on the imported DXF data. After the operation the DXF data is rotated to align with the DesignBuilder X-axis. Normally DXF data will already be orientated to the grid and this command is not required.

Scale DXF drawing

This command allows you to scale the DXF data to be larger or smaller. This may be necessary if the scale of the DXF data was unknown at the import stage. When the command is started click twice to define the end points of a reference line on the DXF data of known length (e.g. a dimension arrow or known length on a building wall). Then either move the cursor to define the new length of the reference line and click again or type in the dimension of the reference line. So a typical sequence might be:

1. Start **Edit > Scale DXF drawing** command.
2. Single click on one end of a large dimension line.
3. Single click on the other end of the dimension line.
4. Type in the dimension in m or ft (depending on the international **units** setting) followed by <Enter>.

Bitmap-based File Types

When the file type is one of the bitmap based formats (PDF, BMP, JPG, PNG, GIF, TIFF collectively referred to here as 'bitmap') the next page of the Wizard provides a preview of the drawing and some options.

Invert bitmap

Check this option if you wish the colours in the bitmap to be inverted. For example if the picture is white on a black background then it will generally be best to invert these for use in DesignBuilder.

Auto scale bitmap after loading drawing

If you wish the 'scale bitmap' command to be automatically started when the Import Drawing File Wizard is closed then check this option.

Quality slider

By reducing the number of pixels in the bitmap it is possible to significantly reduce the size of the imported drawing data and hence speed subsequent drawing 'scale' and 'rotate' operations. The default Quality setting of 0.5 gives a good trade-off between image size and readability but if the drawing file is particularly large you may decide to reduce the quality to reduce the memory overhead or, if the drawing is difficult to read you could increase Quality.

Opacity slider

You can control the opacity (transparency) of the drawing data from 0 to 1. A value of 1 means that the imported drawing will be completely opaque and 0 means it will be completely transparent. The default is 0.5.

Import Drawing File

Preview

C:\Users\darrenf1\Downloads\14775-311C1 - Block B First Floor (A1).pdf

Bitmap-based files may be used for:

1. Existing buildings having paper floor plans that have been scanned into electronic format or,
2. Early stage design sketch ideas are available only in bitmap form.

Note: bitmap drawings do not allow end-point snap like DXF but can be an equally effective option for rapid geometry entry in DesignBuilder.

Editing Bitmap Data

Once the floor plan data has been imported to the model, it must be selected to allow these operations:

- [Move](#) - move the bitmap data.
- [Delete](#) - delete the bitmap data.

Also the **Set X-axis for imported bitmap** and **Scale bitmap drawing** commands are available from the [Edit menu](#) when bitmap data is loaded.

Set X-axis for imported bitmap

Sometimes scanned bitmap files are not exactly aligned to the X-axis and you can use this command to re-orientate the drawing. When the command is started click twice to define the end points of a line in the direction of the X-axis on the imported bitmap data. After the operation the bitmap data is rotated to align with the DesignBuilder X-axis.

Scale bitmap drawing

This command allows you to scale the bitmap data to the correct size using a known dimension in the bitmap image.

When the command is started click twice to define the end points of a reference line on the bitmap data of known length (e.g. a dimension arrow or known length on a building wall). Then either move the cursor to define the new length of the reference line and click again or type in the dimension of the reference line. So a typical sequence might be:

1. Start **Edit > Scale bitmap drawing** command.
2. Single click on one end of a large dimension line.
3. Single click on the other end of the dimension line.
4. Type in the dimension in m or ft (depending on the international [units](#) setting) followed by <Enter>.

Important Note: This process will always be necessary for bitmap drawing formats as the scale is not defined at the import stage.

Partitions

You can also use the imported floor plan data to draw internal partitions. To do this go to block level and draw partitions by tracing over using the floor plan partition data. You should take care to connect partitions to the external perimeters. A common mistake is to snap partitions to DXF data lying very close to the external perimeter but not close enough to create a connection with the external perimeter.

Tip: It is generally best to switch off **DXF snap** in the Drawing options panel when drawing partitions at block level to avoid this problem. Be sure to switch it back on again when you have finished drawing partitions.

Import 3-D Model

DesignBuilder provides interoperability with other software tools through its [gbXML](#) and [IDF](#) import capability. This allows you to import 3-D architectural models created in Revit, Grasshopper, ArchiCAD, Microstation and other BIM systems supporting gbXML data exchange. You can also import EnergyPlus IDF files which can be exported from a number of different energy modelling tools.

Models can be imported from the site or building level using the **Import 3-D models** toolbar icon or use the **File > Import > Import 3-D model** menu command. This opens the **Import 3-D Model** dialog. If you are at site level DesignBuilder will prompt you to create a building first to import the model into.

Unlike the [2-D drawing import](#) which provides only a set of lines for tracing over, importing 3-D models imports the full geometry as blocks with zones, windows, doors and shading surfaces all included. Other construction, glazing and material data can optionally be loaded if it exists in the source model.

Example model imported from Revit into DesignBuilder

Example model imported from ArchiCAD into DesignBuilder

The **Import BIM Model** wizard has two pages which are explained below.

Import 3-D Model

Most of the import controls are the same for gbXML and IDF import.

On the first page you can select the XML or IDF file to import. The file must be in the gbXML or IDF standard data format. Once you have selected the model, press the **Next** button to move to the second page. For large models there will be a delay at this point while the model is loaded to the dialog.

The second page shows a preview of the model along with some controls to control the way the import is to be carried out.

Import Options

View

You can display the preview of the model from various viewpoints. Select from:

- **1-Plan**,
- **2-Left**,
- **3-Right**,
- **4-Back**,

- **5-Front**,
- **6-Axonometric** (3-D view).

Import mode

This option is only available for gbXML imports. Choose whether the importer will base block and zone geometry on the space entities in the source data or on the primary surface elements. The options are:

- **1-Surface** - where the surfaces in the source gbXML data are used to define block geometry. This is the default option as it typically gives the best results for the majority of BIM models imported from Revit and most other BIM applications.
- **2-Space** - where the block geometry is based on the spaces in the source data. This option can give rise to gaps between zones in the DesignBuilder model when (as is usually the case) the spaces do not touch neighbouring adjacent spaces due to the finite thickness of partition walls in the BIM model.

Adjacency tolerance

This is the maximum gap between neighbouring parallel gbXML surfaces that will be interpreted as being an adjacency between 2 spaces. You might enter a value higher than the default 0.01m if the gbXML spaces are separated by large gaps due to thick partitions or ceiling /floor voids being excluded from the gbXML. For example if the largest gap in the between spaces that are to be modelled as adjacent is 0.3m then enter 0.3m here.

The **Adjacency tolerance** can also be updated after the import from the [Advanced tab](#) of the Model options dialog.

Create storey blocks

This option is used to automatically identify stories by grouping adjacent spaces created by extruding from the floor plan with the same upper and lower Z coordinates into single blocks. This has the advantage of making it much easier to later modify internal layouts and it also helps to navigate around large models.

Note: For imported spaces to be grouped into storey blocks, they must all have the same height. To ensure that this is the case, DesignBuilder checks that all non-horizontal surfaces are vertical and all z-coordinates have either the maximum or minimum z-coordinates. Any zones with different ceiling heights will be imported as independent blocks.

Tip: It can sometimes help, especially in lower quality data sets, to import raw surface geometry exactly as defined in the source model. In this case the **Create storey blocks** setting should be switched off and the [Allow open manifold building blocks](#) setting should be switched on.

Import as building blocks

By default this option is selected and the geometric space data will be imported as building blocks ready for use in DesignBuilder modelling. However, you can instead import zone geometry as outline blocks by unchecking this option. The outline blocks give an exact representation of the spaces in the source data and this can be useful for diagnosing any possible problems with geometry. For example if any part of a space intersects with another space then it would not be created as a building block, but it could still be created as an outline block to help you identify and fix any possible issues with intersections in the source model.

Import thermal properties

If this option is selected then DesignBuilder will any load materials, constructions and glazing system thermal properties present in the source data and assign at surfaces and opening level in the DesignBuilder model. In this case, because settings are made at surface and opening levels, the normal inheritance paths used for construction and glazing data will be overridden.

For materials where material thickness is either not specified or is set to 0 a default thickness of 0.05m is applied.

Tip: Since any construction or glazing assignments are set in the DesignBuilder model at surface level, if you need to parametrically adjust construction or glazing surface properties in optimisation, parametric analysis or UA/SA analyses (i.e. they are [design variables](#)), you may need to apply the changes to each surface individually by selecting the appropriate surfaces as [targets](#).

Allow open manifold building blocks

Open manifold (non-enclosed) blocks are a special type of block which can only be created when models are imported from external sources. They have one or more surfaces missing which means that they are not fully enclosed and this has significant consequences on what can be done with the block in the DesignBuilder modeller and in calculations:

- Radiance and CFD calculations cannot be carried out.
- The boolean operations used behind the scenes to manipulate block geometry are not possible and so only limited edit operations may be performed on open manifold blocks. In particular these operations cannot be performed:
 - o [Add surface](#)
 - o [Drag block face](#)
 - o [Mirror](#)
 - o [Divide block using cutting tool](#)
 - o [Boolean geometry operations](#).

Tip: Open manifold blocks are shown in a different shade of grey from normal closed manifold blocks to differentiate them and their icons in the Navigator have a red outline. See screenshot below.

Because Open manifold blocks cannot use all geometry operations, the orientation of their surfaces cannot be reliably determined from the model and DesignBuilder must rely on the orientation data stored with the surface from the source model. This data is not always reliable and so in some cases surfaces are facing in the wrong orientation. The [Flip block surface orientation](#) command can and should be used to check and, if necessary fix, the orientation of surfaces in all open manifold blocks.

Import shading plane surfaces

Shading plane surfaces are specially marked in imported data and so can be treated separately if required. You can choose to import shading surfaces as planes as part of the import or not using this control. Shading surfaces imported into a model will be treated as 2-D flat shading plane surfaces.

Shading Plane EnergyPlus Technical Note

Shading planes are written to EnergyPlus IDF as Shading:Building:Detailed objects since they are considered to be part of the building rather than the site.

Note: Shading plane surfaces do not have any impact on external CFD analyses.

Tip: You can choose whether or not shading planes will be applied to the model using the [Shade Surfaces](#) model option.

Merge co-planar surfaces

If the above Import shading surfaces option is selected then you can choose to either merge any such co-planar surfaces or not.

More information on Importing 3-D models can be found in the [Importing drawing files](#) tutorial

How Does DesignBuilder IDF Import Work?

DesignBuilder [IDF Import](#) is based on a 2 stage process:

1. Convert IDF source data into gbXML.
2. Load the gbXML through the same internal process used for loading gbXML files. More information on that can be found below.

How Does DesignBuilder GbXML Import Work?

The geometric information contained in gbXML includes a collection of surface and space objects which represent the outer and inner volumes of rooms in the parent BIM model respectively. The surface objects are derived from corresponding wall, ceiling, floor etc elements in the BIM and also contain openings for windows and doors. The space objects aren't native to the BIM system but are identified by users through a manual or semi-automatic process. The result of the spatial identification process is a collection of spaces that are separated by gaps that would be filled in the parent BIM model by the BIM primitives such as partitions, slabs, etc.

Internally DesignBuilder includes 2 different ways to import gbXML data:

- **Surfaces** where the gbXML surfaces are used to define the block geometry. In well constructed gbXML data sources this data is used to define the outer block geometry. It avoids the need to see gaps between the blocks caused by partition and internal floor thickness. However if surfaces are missing you may end up with surfaces also missing in the DesignBuilder model leading to open manifold blocks which can't be simulated in daylighting and CFD.
- **Spaces** where surface data is not available the spaces are used as the source of the block geometry.

The DesignBuilder gbXML import works by simply mapping the gbXML space surface geometry to building blocks, one block per zone.

The way to think about the relationship between gbXML "spaces" and "surfaces" is that surfaces define the interlocking zones that make up the whole building model, and the spaces are the inner volume spaces representing the contained air volumes within each zone. So, each internal surface between adjacent zones would generally represent the centre-line between the zones, and the associated record in the gbXML file would reference both zones in the adjacent space field.

Depending on the method used to identify the block geometry they represent:

- In the normal case where DB was able to use surfaces to define the block, the **External measurements Geometry convention template** is applied to give realistic thickness for block surfaces based on the overall thickness of the surface constructions defined in the gbXML if this option was selected.
- Alternatively if DB wasn't able to find enough surface data to define the block but full space data is available then it uses the space *inner* geometry and applies the **Simple Geometry convention template** to give zero thickness for all block surfaces. In this case the building will be made up of a set of blocks

defined based on the gbXML inner spaces, possibly with gaps between them due to the partitions and internal floors.

Note: It is important to understand that in both cases the success of the BIM to DesignBuilder data transfer process depends on how well the spatial identification process has been conducted in the source model. If there are intersecting or missing spaces in a BIM model for example then the model imported into DesignBuilder will generally have corresponding problems.

The adjacency between neighbouring surfaces is calculated within DesignBuilder based on the [Adjacency tolerance](#) setting.

Constructions and glazing systems are assigned to surfaces in the gbXML and when the [Import thermal properties](#) option is selected in the import dialog the constructions assigned in the BIM program will be assigned at surface level within the imported model.

Shading surfaces in the gbXML are retained and displayed in the imported model. Other surface objects aren't normally required and are hidden after the import has been completed but can be activated as shading surfaces from the Model options dialog, Drawing tools tab.

Note: For models imported through the gbXML mechanism, the windows will always be custom. This is true even when importing a model that had previously been [exported](#) from a DesignBuilder model that used the default façade mechanism.

The Revit DesignBuilder Workflow

There is a DesignBuilder add-in for all recent versions of Revit, which can help to ease the workflow when transferring BIM models from Revit to DesignBuilder.

Tip: The [DesignBuilder Revit – gbXML Tutorial](#) contains some useful advice on how to use the Revit to DesignBuilder link to best effect.

Installation

The appropriate Revit add-in is installed when you install DesignBuilder. Ideally the version of Revit you wish to use should be installed at the time you install DesignBuilder. However if this is not the case, you can install the DesignBuilder Revit add-in individually after you have installed the version of Revit you wish to use without reinstalling the whole DesignBuilder application. The DesignBuilder Revit add-in can be installed from the [Downloads](#) section of the website. Note that a different add-in is available for each version of Revit. You should ensure that you install the right version. For example if you are using Revit 2021 you should install the **DesignBuilder Add-in For Revit 2021**.

Note: It is important to understand that the quality of the BIM geometry data ultimately imported into DesignBuilder is directly related to the quality of the geometry included in the gbXML itself. This in turn depends on a) the accuracy of the base Revit architectural model and b) the care with which the analytical model settings were set up prior to the gbXML export.

IDF Import

This page brings together some additional information relating to the IDF import option which can be accessed from the "Import 3-D Model" on page 172

The IDF Import tool allows the building geometry and materials and construction data in EnergyPlus IDF model files to be imported into a DesignBuilder model. All EnergyPlus versions from 7.2 forwards are supported.

In summary the process to use IDF Import tool is as follows:

1. Select the **Import 3-D Model** toolbar icon (above), or use the **File > Import > Import IDF file** menu command.
2. On the first page of the **Import 3-D Model** dialog select the **2-IDF** File type if it is not already selected.
3. Select the IDF file to be imported and press the **Next** Button.
4. On the second page make any selections as described on the "Import 3-D Model" on page 172 dialog help page.

The import may take a while especially if the IDF file is an old version and the IDF data needs updating to the latest version.

The IDF Import processor places a log file in the same location as the main DesignBuilder diagnostics file in the form of IDF_Import_YYYY_MM_DD_HH_MM_SS.log. The latest 10 log files are retained. Any errors in updating IDF files to the latest version ahead of the import are included in the log file.

Supported IDF Versions and Model Objects

DesignBuilder v2025.1 can import IDF files for EnergyPlus v25.1 and earlier.

The following model data objects are supported for import:

General

- Site:Location
- Building
- Zone
- GlobalGeometryRules

Detailed Surfaces

- BuildingSurface:Detailed
- Wall:Detailed
- RoofCeilingDetailed
- Floor:Detailed
- FenestrationSurface:Detailed
- Shading:Site:Detailed
- Shading:Building:Detailed
- Shading:Zone:Detailed

Simple Surfaces

- Wall:Exterior
- Wall:Interzone
- Wall:Adiabatic
- Wall:Underground
- Roof
- Ceiling:Interzone
- Ceiling:Adiabatic
- Floor:GroundContact
- Floor:Interzone
- Floor:Adiabatic
- Window
- Window:Interzone
- Door
- Door:Interzone
- GlazedDoor
- GlazedDoor:Interzone

Materials & Constructions

- Material
- Material:NoMass
- Material:AirGap
- Construction
- WindowMaterial:SimpleGlazingSystem
- WindowMaterial:Glazing
- WindowProperty:FrameAndDivider
- WindowMaterial:Gas
- WindowMaterial:GasMixture

Limitations

- As detailed above the import tool supports the main building and shade geometry, materials and constructions but other IDF data is not imported.
- Use of the zone, surface or opening multipliers is not supported. If any of these multipliers are encountered during an import a warning will be recorded in the log file.
- For materials where material thickness is either not specified or is set to 0 a default thickness of 0.05m is applied.

Merge Model Data From File

It is sometime necessary to accommodate changes made by the architect to a BIM model after significant work has already been done on the energy model on a previous iteration of the design. The **Merge model data from file** command allows you to load all of the important settings from the DesignBuilder model you previously worked on into the latest geometry imported from BIM.

In the descriptions below the "old" model refers to the DesignBuilder model you previously worked on whose settings you wish to import, and the "new" model refers to the DesignBuilder model newly imported from the latest BIM model and needing settings to be imported from the old model.

A typical process is as follows:

1. Create a new DesignBuilder model from the updated BIM model by importing gbXML or through the Revit add-in.
2. In the new DesignBuilder model, use the **Merge model data from file** command to merge the attributes and any components, templates and HVAC system from the previous "old" DesignBuilder model.
3. Check the merge has been completed as required. Note that any newly added blocks, zones, surfaces and openings in the updated model will not receive settings from the old model that was merged in.

When the **Merge model data from file** command is selected a dialog is displayed allowing you to select the "old model" file to be merged into the "new model" with some options. When these settings are confirmed DesignBuilder makes the following changes to the new model:

- Blocks, zones and surfaces are matched between the old and the new geometry based on their geometry and position. Where an object is matched all hard set attributes (those shown in red in model data) are copied over from the old to the new model.
- All user-defined components and templates are copied from the old to the new model.
- If a Detailed HVAC system was defined in the old model then it is loaded to the new model (optional merge). It is important to check that HVAC zone groups contain the right HVAC zones after the merge has been completed.
- Any assemblies defined in the old model are merged into the new model (optional merge).
- Any component blocks defined in the old model are merged into the new model (optional merge).
- Openings such as windows, doors etc are merged based on a user-definable selection. The options are:
 - **1-Retain existing openings** where the new openings are kept and the old ones are not copied over.
 - **2-Overwrite all existing openings** where the old openings are copied to the new model replacing all new openings.
 - **3-Merge non-overlapping openings** where the old openings are copied to the new model wherever possible without overlapping with the openings already in the new model.

Note: The old and new models referred to above must each only contain 1 building.

Tip: The Merge model from file system was specifically created to accommodate the needs of energy modellers working with BIM models that are often in a state of flux, however it can be used in any situation where data is to be merged from one model to another, especially when some degree of geometry matching is required.

Import Building From External File

It can sometimes be necessary to import buildings/blocks from another dsb file into a file that contains an existing model. To do that follow the steps below.

1. Open the model where the building geometry is to be imported to.
2. From the DesignBuilder File > Import menu, click on the **Import building from external file** option and select the dsb file containing the building(s) to be imported. When the import is completed you will end up with the original building and the newly imported building(s) from the external file.

Tip: If you wish to merge selected blocks from the imported building(s) to the existing building you can use the [Transfer blocks](#) tool to move the blocks from the imported building to the existing building. Once you have transferred the blocks you wish to keep you can delete the imported building(s) from the Navigator panel.

Note: Bear in mind that components and templates are not imported with the geometry and attributes when using the **Import building from external file** command. This means that if the building in the external file refers to custom user-defined components or templates that are not also included in the destination model, it is likely that component/template selections will be missing or incorrect in the imported building. For example if the model in the external file includes a custom activity template and it is imported to a model

without that template then you are likely to end up with blank settings where you might expect that Activity template to be selected. **In general you should assume that any custom components and templates and their selections will need to be remade in the imported model.**

Exporting Geometric Data

The model geometric data can be exported in these formats:

- [3-D DXF](#)
- "Exporting gbXML" on page 184

Exporting 3-D DXF

You can export the geometry of the current building model in 3-D DXF format using the Export 3-D DXF model command from the [File](#) > Export menu. This opens the 3-D DXF Export dialog:

Choose one of two options:

- **1-Whole model with details** - The entire building model is exported including 3-D details such as window frames, 3-D building elements etc. This option can be useful for exporting for visualisation and further processing in other software such as SketchUp (image below)
- **2-Zones** - The building model is exported showing only zones. This option can be useful for visualising the geometry of the model used in simulations.

Note: DesignBuilder DXF output uses surface objects and not lines so be sure to select one of the shaded surface view options in your DXF viewer. Wire frame views will not display the model.

Example 3-D DXF Output - Whole model with details

The above model was created in DesignBuilder, exported in DXF format using the **Whole model with details** option and Imported into SketchUp where details such as textures, trees and people were added.

Note: when importing DXF files into SketchUp be sure to set the units options on the Open dialog to Metres.

Exporting GbXML

You can export the current building model in gbXML format using the **Export gbXML model** command from the [File](#) > Export menu. This opens the gbXML Export dialog. Press OK to confirm and select the name of the gbXML file to be created.

The gbXML file includes full surface geometry, zone lists with names, windows, doors, component block shading devices, constructions, materials and glazing systems. Note that all other data is not exported. No data is stored on activity, lighting, HVAC and model settings.

gbXML files exported from DesignBuilder can be imported into any other software supporting the gbXML standard file format, including DesignBuilder v3 and later.

Tip: It is not generally possible to load models saved in DesignBuilder dsb format into earlier versions, but as an alternative you can export gbXML from a recent version and import that into earlier versions of DesignBuilder supporting the gbXML import. While this method would not retain most model data settings it would allow you to transfer the data listed above.

Working With Buildings (Site Level)

At the site level you can:

- [Add new buildings](#),
- [Copy, delete and change the position](#) of existing buildings.
- Change the [site orientation](#).
- Enter [site model Data](#) including information on the site location, weather data etc.

Add New Building

You can add one or more new buildings from the site level. Each building has its own set of [Model options](#) and is simulated separately but shares [site Model data](#) with the other buildings on the site.

When you select the Add new building option you are presented with the **Add new building** dialog which allows you to make some basic settings:

- [Building](#) - basic setting for the building model
- [Default Data](#) - defaults for Construction, Activity, Glazing, Lighting and HVAC

When you press OK to close the dialog the building is created with the various selected settings and in most cases starts you in Draw block mode so you can start adding geometry straight away. If you are not ready to do this simply press the <Esc> key or right click and select Cancel.

See also the [Starting a new project](#) tutorial

Including Multiple Buildings On The Site

You can add as many buildings to a site as you like, however there are some considerations to bear in mind when more than one building are to be included on a site. These are listed below.

1. You can obtain snaps from other buildings when moving or copying buildings at site level, however it is important to be aware that buildings do not share adjacencies with each other. In other words, you may have positioned Building A so that one of its façades is adjacent to the façade of a neighbouring building, but that does mean that there will be an internal adjacency set up between the 2 buildings - the touching façades of the 2 buildings will be simulated using external surfaces.
2. Snap points from other buildings are not available at building level or below, so if you need to accurately align buildings with each other you may need to go to site level and move them into position.
3. Other buildings can be accounted for in EnergyPlus and Daylighting simulations by selecting the appropriate calculation options. For both [EnergyPlus](#) and [Daylighting](#) the other buildings can cast shadows and provide reflections, but they cannot be simulated within the same calculation.
4. Each building on the site adds to the memory overhead, especially if large amounts of result data are stored. So if buildings and/or their stored result sets are likely to be large, when planning your modelling, you may consider including each building in a separate model and simulating the shading/reflectance effects of neighbouring buildings using component blocks.

Add New Building - Building Tab

Model Type

Type

Select the type of building model you wish to create from the list of options. Your selection will depend on what you want to do with the building model and the amount of data available. Some typical options are:

- **Default** - Recommended default settings for general-purpose modelling.
- **Architect early stage design** - Early design stage analysis of building components, façade and cooling options.
- **Detailed design with HVAC** - If you plan to use the [Detailed HVAC](#) model option then select this option.

- **Parametric building + standard data** - Add a building of standard form (rectangular, L-shaped or courtyard) without needing to draw anything.
- **Calculated natural ventilation** - Airflows are calculated using the EnergyPlus multizone AirflowNetwork based on wind and stack pressure differences.
- **ASHRAE 90.1** - The template to be used for ASHRAE 90.1 models which sets Detailed HVAC and other appropriate model options. This selection is forced for [ASHRAE 90.1 models](#).

Tip: Regardless of the selection you make here, you can fine tune the Model options later after having created the building using the [Model options dialog](#).

Geometry convention template

Select the geometry convention template to be used for this building model. You can easily change this at any level in the model on the Constructions tab under the [Geometry, Areas and Volumes](#) header.

ASHRAE 90.1 building type

If this is an ASHRAE 90.1 model then you can select whether it is a proposed or baseline model. In most cases you will start by creating a proposed model and create the baseline model from this. Options are:

- **1-Proposed** and
- **2-Baseline**.

Add New Building - Default Data Tab

This tab allows you to define the templates used to populate the new building with default Model Data.

Construction

Select the construction template to use as a source of default fabric data for the building. By default DesignBuilder will select the Reference construction template for the current region, or, if a building has been added previously, then the templates selected the last time a building was added are provided as defaults.

Activity

Select the activity template to use as a source of default activity-related data for the building. This will set the following default data:

- Occupancy levels and timing, holidays etc
- Metabolic rates
- Levels of equipment use
- Heating and cooling temperature setpoints
- Illuminance requirements
- Fresh air requirements

Glazing

The glazing template is used as a source of default window, shading and percentage glazing data for the building.

Lighting

The lighting template is used as a source of default lighting and lighting control data for the building.

HVAC

The HVAC template is used as a source of default data for the HVAC equipment to heat and cool the building.

Working At Building Level - Blocks And Solar Collectors

At building level you can:

- [Add Blocks](#) - Building blocks, Component blocks and Outline blocks.
- [Edit Block geometry](#) using a range of different block editing tools.
- [Add Solar collectors](#) - PV and solar hot water.
- "Edit Openings at Building Level" on page 251

The rest of this topic about adding various types of block.

Blocks are the basic elements used to create a 3-D DesignBuilder model. Three types of block can be added to the building:

- [Building Blocks](#) are the mechanism used in DesignBuilder to create 3-D building volumes. They are often referred to in simply as Blocks and are composed of building elements such as walls, floor slabs and roofs . Building blocks may be partitioned internally to form a number of zones.
- [Outline Blocks](#) are used to help in the creation of more complex building block geometry.
- [Component Blocks](#) are used to create visual, ground and shading structures which do not contain zones.

Blocks of all types are created at the Building Level in the same way and are drawn using [perimeters](#) which can be extruded either horizontally, vertically, or in any other direction.

This section describes the various operations involved in [creating](#) and [editing blocks](#) at the building level.

To create or edit a block you must first go to the building level and you can do this by clicking on the building entry in the navigator or if you're at the site level and you want to edit an existing building, you can double-click on the building in the 'Edit' screen.

Either operation will take you to the building level:

Adding Blocks

To add or create a new block, first go to the building level (if you are not already there) and click on the **Add new block** tool. If you've just created a new building, the Add new block tool is automatically activated. A block is created by drawing the base perimeter of the block using one of the perimeter shapes such as a polygon. The [dimensions of the block](#) are those measured from the outside, the height of the block is the floor-floor height.

See also these tutorials: [Starting a new project](#), [Blocks and dimensioning protocols](#) and [Adding blocks and using the measure tool](#)

Please refer to [perimeter shapes](#) for details of drawing perimeters. After drawing a perimeter, a block will be automatically extruded by the [Height](#) entry in the 'Drawing options' settings or if the [Auto-complete block](#) setting is switched off, the perimeter can be dragged to form the extrusion. To help in setting the correct extrusion height, the [increment snap](#) setting can be used which enables the drag movement to jump by any defined increment. Alternatively, you can simply type in an extrusion height and press the enter key:

When a block has been placed, additional blocks can be drawn onto any surface of the block to form more complex aggregate blocks. As you move the mouse cursor across the faces of an existing block, each face will change colour from grey to blue to indicate the active drawing plane. You can lock the active drawing plane by pressing the SHIFT key, which allows you to move the cursor off the current face while keeping the plane active. You can also lock the active drawing plane to the ground plane by moving the cursor over the background area and pressing the SHIFT key, this is particularly helpful in avoiding the selection of the wrong plane when drawing a vertically extruded block adjacent to an existing block. Once you've clicked the first data point into the active drawing plane, it becomes locked regardless of whether or not the SHIFT key is pressed until the perimeter has been completed or the tool is cancelled. In the example below the vertical plane shown in blue has been selected, the shape of the block will be drawn in this plane and the volume created by extruding normal to it.

When a block is added to the surface of another block, a geometric [link](#) is automatically created between the two blocks:

A [hole](#) can be added to the mating surface of this link (the [inter-block partition](#)) in order to form one contiguous space:

Note: the [Merge zones connected by holes](#) Model option must be set if you wish the two zones in the 2 blocks to be treated as one zone in the thermal calculations.

As already illustrated, a block perimeter can be drawn on the ground plane or onto the surface of an existing block in which case the perimeter is extruded normal to the surface on which it is drawn.

Avoiding Indents

If the perimeter includes indents in such a way that the requested wall thickness is physically impossible and the wall thickness cannot be accommodated then DesignBuilder will still allow the block to be created but the wall thickness is reset to a small value (typically 0.025m). See the wall thickness topic for more on this.

Drawing in a vertical plane without reference to an existing block

To create horizontal extrusions from a vertical plane, the first perimeter line can be aligned with the Z-axis using the [axis snap](#):

The [protractor](#) can be used to place the second line in order to accurately define the orientation of the plane relative to the base or ground plane:

Alternatively, the orientation of the plane can be defined using the first line:

Snapping the second line to the Z-axis then forms the horizontal extrusion:

Once a vertical plane has been defined it will be 'remembered' until the 'Add new block' command is cancelled, so the perimeter can be 'unwound' using the ESC key or the right-click menu 'Undo last point' entry and any perimeter shape drawn into the stored plane:

After drawing the last perimeter line to connect to the perimeter start point, the perimeter can then be dragged to create a horizontally extruded block:

Block Creation Options

The block creation options enable you to control the way a block is drawn:

- "Block and Zone Dimensions" on page 194
- [Block types](#)
- [Block Form](#)
- [Height](#)
- [Auto-complete block](#)
- "Follow Path" on page 219

These options are accessed through the **Drawing options** data panel, which is displayed when you click on the [Add new block](#) tool:

Block And Zone Dimensions

See also: [Geometry Areas and Volumes](#)

The diagram below illustrates how blocks should be defined and how zone volumes and surface dimensions are derived from the parent block. Note that there are 2 alternative dimensioning protocols:

- **UK NCM Convention** which should always be used when using DesignBuilder for assessing buildings through the UK National Calculation Methodology, i.e. for Part-L and Section 6 Building Regulations checks and EPC/BER calculations.
- **Simulation and General Design Convention** which should generally be used for all other applications where an NCM calculation is not required.

Schematic Illustrating Two Alternative DesignBuilder Block Dimensioning Conventions

The main differences between the 2 conventions are:

1. **UK NCM Convention** - For ground and intermediate floors, the block height is defined as "top of floor to top of floor" and for top floor blocks with a flat roof the block height is "top of floor to soffit/underside of roof slab". Details on defining building geometry for other less common geometries when using the NCM can be found in the [Non Domestic EPC Conventions for England & Wales](#) document.
2. **Simulation and General Design Convention** - For ground floors the block height is "top of floor to bottom of floor". For intermediate floors, the block height is defined as "bottom of floor to bottom of floor" and for top floor blocks with a flat roof the block height is "bottom of floor to soffit/underside of roof slab".

The important points to note for **both conventions** are:

1. The length/width dimensions of the block are measured from the outside of external walls.
2. Zone height is always the same as block height, i.e. it is unaffected by block wall thickness or thickness of floor constructions.
3. Wall surfaces extend the full height of the block.
4. Flat roofs are placed on top of the block, so when drawing a block with a flat roof you should exclude the [roof](#) construction in the height.
5. External floors are placed under the block, so when drawing a block with an external floor you should exclude the [external floor](#) construction thickness in the height.
6. Zone surface dimensions (shown in green dotted lines above) are measured from inner edges of outer walls and the centre line of partitions.
7. Floor surfaces extend horizontally to the inner surface of external walls and to the centre line of partitions. See below for more on zone/surface dimensions.

The zone **volume** used in ventilation calculations is the actual inside volume (shown in yellow in the diagram above). These inside zone surface dimensions are used to define surface heat transfer areas in simulations and other calculations.

Zone perimeter (plan view)

Other related information

1. See [Constructions](#) topic for information on the meaning of the Construction Model data.
2. Also see [Constructions](#) for how to edit the construction configuration.
3. Block wall thickness for information on how zone inner volumes are created from external block dimensions
4. [Construction and glazing](#) model options for details of volume calculations with the options to include/exclude floor and ceiling volumes from the zone volume used in the energy calculations.
5. And the Model Geometry Example section for a detailed worked example illustrating how surface areas and volumes are calculated.

See also the [Blocks and dimensioning protocols](#) Tutorial

Block Types

Four types of block are available:

- [Building Blocks](#) are used to draw the model or a section of the model.
- [Outline Blocks](#) are used to help in the creation of building block geometry and do not affect the model.
- [Component Blocks](#) are used to create visual and shading structures which do not contain zones.
- "Assembly Block" on page 207 are assemblies of component blocks, typically used for modelling building details and equipment in CFD or for more complex façade shading structures.

Tip: If you find you have accidentally created a block of the wrong type, you can convert it the required type using the [Convert Blocks tool](#).

Building Block

A building block represents the outer shell of the model or part of the model. A finished block comprises a set of building elements, which may include external walls, roofs and floor slabs, the constructions of which are determined from the current building [construction model data](#). Similarly, using [opening model data](#), block facades are automatically created with the required configuration of windows, doors, vents and solar shading devices:

Solar shading devices are displayed in the [visualisation](#) screen:

A block may be divided internally into any number of zones by drawing [partitions](#) and where needed, voids or [courtyards](#) can also be incorporated:

Custom [openings](#) (windows, doors, etc.) can be added to block facades by going to the surface level and using the 'Draw window' family of commands:

Blocks can be [moved](#), [copied](#) and [rotated](#). Blocks can also be [cut](#) or [stretched](#) and block faces can be [dragged](#) to different positions.

Outline Block

An outline block is created and edited in exactly the same way as a building block but is just a 3-D shape without associated building elements such as walls, floors, roofs, etc.

Outline blocks are very useful in the creation of more complicated models. Because they are relatively simple objects, they are much faster to create, copy, move, etc. than conventional building blocks and can be manipulated freely without worrying about intersections. Once the required geometry has been established, outline blocks can be converted to conventional blocks.

Outline blocks can also be used as a temporary device to create drawing planes from which building blocks or other outline blocks can be extruded.

Note: Because Outline blocks are not part of the model (in the same way that [construction lines](#) are not part of the model) they do not appear in the Navigator panel.

You can remove all outline blocks from a model by selecting **Remove all outlines** from the [Edit](#) menu.

Basic use of outline blocks is covered in the [Outline blocks, Boolean operations](#) tutorial

Using Outline Blocks To Create A Dormer Window

For example, to create a dormer window, first set the [Block type](#) to **2-Outline block** and lock the active drawing plane to the front surface of the first floor block by selecting it and pressing the SHIFT key, then draw the base line of the dormer face perimeter:

Create the angle of the dormer pitch using the [Protractor](#):

and then complete the perimeter:

Now drag the dormer perimeter all the way through the main roof block:

Select the dormer block and click on the [Cut block](#) tool, making sure that the Cutting method on the Drawing options data panel is set to **2-Select plane** and click on the forward facing plane of the main roof block to create a cut in the dormer block in the plane of the roof:

Click again to finish the cut and then select the section of the dormer block that is not required and delete it:

Select the dormer outline block and click on the [Convert outline block](#) tool to complete the process:

The finished block after adding openings:

Drawing dormer roofs is also illustrated in the [Dormer Roof Tutorial](#)

Note: Sometimes when converting outline blocks to component or building blocks you will notice that the new block has a very slightly different size to the original outline block. This can happen when DesignBuilder needs to slightly adjust the size in order to generate a viable zone with 3-D slab surfaces. It is therefore advisable when using outline blocks to create complex geometries to draw and convert the outline blocks individually. This avoids adjacencies between touching outline blocks from getting 'broken' when they are converted 'en-masse'.

Component Block

There are 3 types of component block:

- [1-Standard](#) - used for shading, reflection and visualisation.
- [2-Ground](#) - used for setting ground adjacency, shading, reflection and visualisation.
- [3-Adiabatic](#) - used for setting adiabatic adjacency for modelling adjacent buildings at similar conditions, shading, reflection and visualisation.

Component blocks are drawn in the same way as Building blocks but selecting the [Block type](#) in the Drawing Options panel to be **3-Component block**.

Each Component block has its own Component block material, transmittance schedule and shade/not shade [model data](#). To edit this you must first go to the component block itself by double-clicking on it in the model edit screen or clicking on the entry in the Navigator. Alternatively, component blocks inherit default model data from the building level so if you leave the component block model data in its default state (blue) you can change all model data in one go by making the edit at the building level.

All component blocks cast shadows in [Visualisations](#). In Radiance daylighting calculations component blocks both cast shadows and provide diffuse and/or specular reflection.

Standard Component Block

Sometimes it can be useful to create structures such as pillars, shading obstructions and balconies which do not contain zones. **Standard component blocks** can be used for modelling such structures as they are treated simply as shading/reflection surfaces in simulations without any zones.

Standard component blocks are visible in [Visualisations](#), using the texture associated with the [Component block material](#) as set on the [Constructions tab](#) under the Component Block header. They can be used to cast

shadows and reflect solar radiation and light in EnergyPlus simulations by checking the [Component block shades and reflects](#) model data under Component Blocks on the Constructions tab.

Note: In EnergyPlus simulations, component blocks do not shade ground reflected solar radiation and light unless the [Model all external reflections and shading of ground reflected solar](#) calculation option is used.

The image below shows some typical uses of Standard component blocks.

Important Note: Component blocks do not absorb or conduct heat in any way - their only effect on building surfaces in simulations is related to the shading and reflection of short-wave solar radiation and light.

Component blocks are a flexible way to apply shading to any part of the building and can be used to model more complex window shading systems not catered for by the in-built [local shading](#) systems that can be selected on the Openings tab. However there are some issues that should be considered when using component block in this way and these are discussed in the [Component blocks used for local shading](#) reference page.

Note: Standard component blocks can be added at building and block levels, but **component blocks added at block level are not used in EnergyPlus simulations**. They are however used in CFD, Daylighting and Visualisation.

More information can be found in the [Shading using standard component blocks](#) tutorial.

Adding component blocks to assemblies

One or more component blocks can be combined into [assemblies](#) and stored in the [Assembly library](#). Assemblies are used in EnergyPlus simulations for shading in much the same way as standard component blocks. The same rules as described above apply in that they are used at building level in EnergyPlus simulations, and at both building and block level for CFD, Daylighting and Visualisation.

One important advantage of using assemblies over component blocks is that it is possible to edit the size or form of one instance of an assembly and all similar instances are automatically updated as well. This allows a large number of geometries to be edited in once go which can be useful for quickly editing façade geometry for example.

Ground Component Block

Ground component blocks can be used as a convenient way to set the adjacency of any touching building block surfaces as being 'adjacent to ground'. In the model below the Ground block (shown in green) has been positioned in contact with the building block to create a ground adjacency in the part of the Building block surface in contact with the Ground block.

Ground component blocks are visible in [Visualisations](#), using the texture associated with the [Component block material](#) as set on the [Constructions tab](#) under the Component Block header. They can be used to cast shadows and reflect solar radiation and light in simulations by checking the [Component block shades and reflects](#) model data under Component Blocks on the Constructions tab.

Note: It is important to understand that the ground component block is used only to modify the adjacency of the surfaces touching it to be 'adjacent to ground'. The areas of the zone surfaces that do touch the ground component block are treated as being adjacent to the [monthly ground temperatures](#) defined for the site. **The material associated with the ground component block and the thickness of the block are not used in any way to modify the conduction path of heat from the building to the ground.** To modify the properties of the ground heat transfer, edit the [ground construction](#).

Surfaces with any openings which touch a ground component block will have those openings removed when the component block is placed. Also it is not possible to add openings in parts of a zone surface that touch a ground component block. This applies to sub-surfaces as well as windows, doors, vents and holes.

View from zone level

Ground component blocks are displayed in the visualisation screen using the [Ground texture](#) as set at the site level.

More information on ground modelling can be found in the [Ground Modelling](#) topic.

Note: The adjacencies established by contact with ground blocks can be overridden by making settings under [Adjacency](#) in Constructions model data at the surface level.

More information on how to work with ground blocks can be found in the [Setting adjacency conditions using ground and adiabatic blocks](#) tutorial.

Adiabatic Component Blocks

Adiabatic component blocks can be used as a convenient way to set the adjacency of any touching building block surfaces to 'adiabatic'. Adiabatic surfaces do not transfer heat beyond their outer surface and are often used for modelling boundaries with other spaces that can be considered to be at roughly the same temperature as the zone. In the model below the Adiabatic block (shown in red) has been positioned in contact with half of the South facade of the building to model the effect of an adjacent building which does not form part of the DesignBuilder model. The touching adiabatic component block creates an adiabatic adjacency in the part of the Building block surface in contact with the Adiabatic block.

Adiabatic component blocks are visible in [Visualisations](#), using the texture associated with the [Component block material](#) as set on the [Constructions tab](#) under the Component Block header. They can be used to cast shadows and reflect solar radiation and light in simulations by checking the [Component block shades and reflects](#) model data under Component Blocks on the Constructions tab.

Effect of Adiabatic boundaries on heat transfer

Note: While no heat is conducted across the outer side of adiabatic surfaces, these surface will still allow the flow of heat at the inside surface into the structure and so act to provide thermal mass to the connected zone. **Therefore simulation results will show heat transfer for adiabatic surfaces.** In thermally massive constructions (e.g. concrete floors) these heat flows can be quite significant over the period of hours and days, but usually less so over monthly intervals.

Note: All openings and sub-surfaces in adiabatic surfaces are ignored in EnergyPlus simulations

More information on how to work with adiabatic blocks can be found in the [Setting adjacency conditions using ground and adiabatic blocks](#) tutorial.

Assembly Block

An assembly block (or just assembly) is a collection of (usually connected) [component blocks](#) used to create an object of some sort. Assemblies can be used to create internal objects such as furniture, people, stairs, or external objects such as shading systems, trees or buildings.

Custom assemblies can be created from existing component blocks that you draw and are added to the "Assembly Library" on page 648 before being placed. Once added to the library they can be loaded to the model ([placed](#)) either at building level (external assemblies) or at block level (internal assemblies).

Some typical applications of assemblies are:

1. Creating internal objects with CFD boundary conditions, such as occupants or screens with convective gains spread over their surface.
2. Creating shading devices for EnergyPlus simulations, cooling design calculations and daylighting studies.

In general, assemblies are used and behave very much like [standard component blocks](#). Like component blocks, assemblies are used at building level in EnergyPlus simulations, and at both building and block level for CFD, Daylighting and Visualisation. They can be used to shade and reflect in EnergyPlus simulations and Radiance daylighting calculations and they show up on visualisations using the texture associated with the material selected for the underlying component blocks. If different component blocks within an assembly have different materials selected then the assembly is displayed with corresponding multiple textures as shown below.

One important advantage of using assemblies over component blocks is that it is possible to edit the size or form of one instance of an assembly and all similar instances are automatically updated at the same time. This allows a large number of geometries to be edited in once go which can be useful for quickly editing large amounts of façade geometry.

Note: To edit the form of an assembly so as to make the same edit to all other similar assembly instances you must first navigate down to the assembly and edit the form of the underlying component block(s). The [Add surface](#), [Drag face](#) and the [Cutting](#) block edit tools can be used in this case. It is possible to edit individual assemblies without affecting similar instances by making the edit using the [Stretch](#) tool while at building level. This is the only block edit tool that can be used to change the form of an assembly without affecting the other instances.

Placing Assemblies

Once an assembly has been added to the library it can be placed either at building or block level. For example to place a chair assembly from the library (DesignBuilder comes with a small assembly library which includes a chair):

1. Navigate to the block where the chair is to be placed.
2. Click on the **Place assembly** icon 
3. The Drawing options panel is displayed in the bottom left of the screen.

4. Select the Chair assembly from the dropdown list of available library assemblies.

5. If you would like to change the dimensions of the chair to be placed (or its offset from the floor plane) you can do so by changing any of the Offset, Width, Height, Depth and X, Y, Z Scale settings in the Drawing options panel.
6. Move the mouse to the location in the block where the chair is to be placed. As you move the mouse around the block different selection planes become available. In this case you will place the chair on the floor. Note that the place where you click on the floor will position the part of the chair that was defined as the [attachment point](#) when the assembly was added to the library.
7. Click to define the location of the assembly attachment point.
8. Now define the orientation of the chair by moving the mouse. It is usually easiest to move the mouse away from the object being placed during this process to give you the finest control. As you move the mouse the rotation of the chair will be adjusted. Once the rotation of the chair is as required click again with the mouse to complete the placement.

9. The Place assembly command remains active allowing you to place more assemblies. To close the command press the <Esc> key.

See also:

- "Assembly Library" on page 648
- "Component Blocks & Assemblies as CFD Boundaries" on page 1924

Block Forms

While drawing a block perimeter, you can select the block form from the Drawing options data panel in the bottom left of the screen. The standard block forms are provided to facilitate the creation of blocks representing specific building geometries. You can select from options 1-4 below:

- [1-Extruded](#)
- [2-Sloped wall](#)
- [3-Pitched roof](#)
- [4-Dome](#)
- [\(5-General\)](#)

The **5-General** block form is not selectable but rather is defined internally by DesignBuilder following block geometry operations such as [Cut block](#), Horizontal block extrusion, [Drag face](#) and [Boolean geometry operation](#).

Once a block has been created, it is possible in most cases to change to a new form by navigating to the block and opening the [Model options](#) dialog. When at block level the Model options dialog opens at the [Block tab](#) and there the Block form can in most cases be changed.

Extruded Block Form

The Extruded [block form](#) is the most commonly used geometry. You create an extruded block by drawing a [perimeter](#) using a number of pre-defined shapes and then extruding the perimeter by whatever distance is required. If you use the polygon perimeter [shape](#) you can create extrusions in both horizontal and vertical planes (or even in sloped planes).

The various methods of drawing general extrusions are explained under [Adding Blocks](#). Circular and rectangular perimeter [shapes](#) are used to create cylindrical and rectilinear prismatic extrusions from horizontal planes:

See also the [Blocks and dimensioning protocols](#) tutorial.

Sloped Wall Block Form

The Sloped wall [block form](#) is used to create blocks on horizontal planes with uniformly sloping walls. Sloped wall blocks can be created using any perimeter [shape](#) (polygon, rectangle or circle):

The wall angle is defined using the **Slope** setting in the Drawing options panel and the blocks are automatically truncated by the **Height** setting:

Geometry	
Block type	1-Building block
Type	2-Sloping walls
Slope (°)	50
Height (m)	3.00
Perimeter	
Shape	1-Polygon
Line type	1-Straight line
Thickness (m)	0.292
Protractor >>	
Direction Snaps >>	
Point Snaps >>	
Drawing Guides >>	

Pitched Roof Block Form

The pitched roof [block form](#) automatically generates a pitched roof from a perimeter drawn on a horizontal plane. Pitched roof blocks can be created using any perimeter shape (polygon, rectangle or circle):

The slope of the roof is defined using the **Roof slope** setting in the Drawing options data panel. A pitched roof can be created with hips or gable ends using the Gable roof setting:

If you draw a pitched roof on top of an existing block, you can control the overhang or the depth of the roof eaves using the **Roof overhang** setting:

See also the [Adding a roof, construction lines](#) tutorial

Voids

Where roofs are to be created on top of conventional blocks that contain voids and the voids are to be automatically incorporated within the pitched roof, the [Automatically include voids from lower blocks](#) Model options switch must be switched on before drawing the roof perimeter.

Pitched Roof Drawing Options

Gable roof

Check this option if the roof is to have vertical gable ends (see above). If this option is not checked then the roof geometry will be a 'hip roof'.

Roof overhang

The extent to which the roof forms an overhang over the zones below. If the [Auto-calculate pitched roof thickness](#) option is checked then the overhang displayed in the model and also the overhang modelled in the simulation will be exactly the value of Roof overhang entered here.

Roof slope

The slope of the roof to be generated measured from horizontal.

Roofspace occupied

If the roofspace is flagged as being unoccupied (this option is left unchecked) then a series of changes are made to the block attributes:

- Any glazing that would otherwise have been included on the gable end walls is removed.
- [Zone type](#) is set to **2-Semi-exterior unconditioned**.
- Infiltration in the roofspace has a default value of 1 ac/h when using [Scheduled](#) natural ventilation or 'Very poor' sealing quality when using [Calculated](#) natural ventilation.

Automatic Pitched Roof Geometry

This section describes the automatic DesignBuilder pitched roof geometry generation with reference to an example roof created by drawing a rectangular perimeter with a roof overhang of 0.3m and a roof slab thickness of 0.2m:

Roof perimeters are drawn using the perimeters of lower adjacent blocks:

The software first creates the roof zone (this would be the zone written to the EnergyPlus IDF file) by first identifying the wall thickness of the adjacent lower block and then deflating the drawn perimeter by this thickness to obtain the basic roof zone perimeter. The resulting roof zone perimeter is then guaranteed to coincide with the lower adjacent zone perimeter(s) in the absence of a roof overhang:

If a roof overhang is specified, the basic roof zone perimeter is then inflated by the roof overhang:

The roof zone is then completed by identifying the skeleton of the perimeter and applying the specified slope to the resulting segments. The base of the roof zone now overlaps the lower adjacent zone(s) by the specified roof overhang:

Note: In the case where a roof perimeter is drawn on top of several blocks having different wall thicknesses, the software identifies the wall thickness having the longest perimeter and uses that thickness to derive the roof zone perimeter. You should be aware that in this case the specified roof overhang will only be guaranteed where the roof overlaps blocks having the same wall thickness as that identified for the roof zone perimeter.

The roof building block slabs are then created by extruding the roof zone surfaces outward along a normal to the surfaces by a distance specified using the Roof Thickness setting.

The perimeter of the resulting roof block will extend beyond the roof zone perimeter by a distance (d in the illustration) determined by the specified roof thickness:

Note: The overhang created by the formation of the roof slabs (d in the above illustration) is only noticeable in the Edit and Visualisation views and will not be written to the IDF file i.e. unlike the roof zone overlap, it has no effect on the EnergyPlus shading calculations.

Gable roofs

If the Gable roof option is selected, all gable end roof segments (isosceles triangles) are generated to fit flush with the lower adjacent block surface:

If the specified gable wall thickness is different to the wall thickness of the lower adjacent block, an overlap will be created between the roof zone and the lower adjacent zone, which may affect shading calculations in EnergyPlus:

Note: Pitched roof form blocks are automatically configured so that the external walls are not shown on the Edit screen when at block level. This can help when drawing partitions, positioning assembly blocks etc. The option can be reversed using the Display external walls Block display model option if required.

Dome Block Form

The dome [block form](#) is used to create hemispherical blocks and can only be created using the circular perimeter shape:

More information on using the Dome block form can be found in the [Drawing arcs, circles and domes](#) tutorial

General Block Form

When a block is edited in such a way that it no longer fits with one of the standard block forms ([Extruded](#), [Sloped wall](#), [Pitched roof](#) or [Dome](#)), it is labelled by DesignBuilder with the **5-General** block form.

Blocks having the General block form can still be transformed back to have the Sloped wall or Pitched roof form (but not the Extruded form) on the [Block tab](#) of the Model options dialog.

Note: General form blocks are automatically configured so that the external walls are not shown on the Edit screen when at block level. This can help when drawing partitions, positioning assembly blocks etc. The option can be reversed using the Display external walls Block display model option if required.

Height

After drawing a vertically extruded block perimeter on a horizontal plane, the block will be automatically extruded using the Height setting, if the [Auto-Complete Block](#) option is switched on or the [View Rotation](#) has been set to 'Plan'.

See also the [Blocks and dimensioning protocols](#) tutorial

Auto-Complete Block

After drawing a vertically extruded block perimeter on a horizontal plane, the block will be automatically extruded by the [Height](#) setting if the Auto-Complete Block option is switched on or the [View Rotation](#) has been set to 'Plan'. With this option switched off (or in the case of a non-horizontal drawing plane), the perimeter can be dragged along an axis normal to the perimeter to obtain the required extrusion.

See also the [Blocks and dimensioning protocols](#) tutorial

Follow Path

The **Follow path** tool allows a new block to be added to the model by drawing a block profile and extruding it along a path to create the 3D form. Both the block profile and the path are created by drawing [construction line streams](#).

The **Follow path** tool is similar in concept to the [Drag face](#) tool but it can also turn corners and follow any non-intersecting path, so curved block shapes or wrap-around shades can be created.

The process is described below using an example to illustrate:

1. Start at building level.
2. Draw a closed loop using a construction line stream to represent the block profile. The closed loop block profile must be orientated vertically.
3. Draw a second construction line stream to represent the path that the block profile will be extruded along. The path stream must touch the block profile stream at its end point and lead away from the face in a perpendicular direction following a horizontal route.

4. Once both the block profile and path streams have been created, select all of the construction lines in the block profile stream. It is usually easiest to do this using a selection rectangle.

5. Select the **Edit > Follow path tool** menu option or use the <Ctrl + Shift + T> keyboard shortcut. The block profile construction lines will turn from dark blue to light blue (cyan).

6. Select the path construction line stream by clicking on the stream once with the mouse. When selected, the stream of construction lines representing the path will be displayed as a thicker dark blue line.

7. Select the type of block to create in the Drawing options panel. In this example the **3-Component block** option is selected.
8. Click with the mouse anywhere on the model to create the new block.

Newly created curved component block

9. Once the block has been created the construction lines are no longer needed and can be deleted.

Tip: Although the current **Follow path** tool only works for vertical closed loop profiles and the path needs to be horizontal, you can rotate the horizontal path extrusion to any required orientation.

Note: **Follow path** requires more than one construction line segment to be present in the path stream, i.e. it cannot just be a straight line.

View a [video showing how to use the Follow Path tool](#) to create a roof shading surface.

Edit Blocks

The geometry and other attributes of blocks can be modified using the following tools:

- [Drag block face](#)

- [Divide block using cutting tool](#)
- [Boolean Geometry Operations](#)
- [Edit Block Geometry Dialog](#)
- [Convert Outline Block](#)
- [Transfer Blocks](#)
- "Add Surface" on page 248

Drag Face

The topology of a block can be edited using the **Drag face** tool which allows you to select a block surface and drag it along an axis, normal to the surface. To edit a block topology first go to the building level and click on the **Drag face** tool. Then move the mouse cursor to the block face that you want to move. As you move the cursor across the block surfaces, each surface will highlight to help in selecting the required surface. When the mouse cursor is over the required surface, click to start dragging it:

Drag the surface using the mouse or key-in the distance to shift the surface by the required amount:

See also the [Stretch, drag face and rotate tools](#) tutorial.

Divide Block Using Cutting Tool

Blocks can be cut (i.e. divided into 2) using the **Divide (Cut) Block** Tool. To cut or divide a block first go to the building level, select the block that you want to modify and click on the Divide block toolbar icon. Blocks are divided using a plane which can be defined using one of 2 methods:

- **1-Draw plane** - you define the plane by clicking on 3 points.
- **2-Select plane** - you define the plane by selecting an existing plane in the model.

See also the [Cutting blocks, protractor tool](#) tutorial

Draw Plane Method

The **Draw plane** cutting method involves drawing two lines which define the plane. For example to cut a pitched roof to fit flush with a rotunda:

Because the geometry is fairly complicated, it's advisable to use an [outline block](#) to generate the intermediate geometry and then convert the block to a [building block](#) after the editing process is complete. So, from the building level, click on the [Add new block](#) tool, select **2-Outline block** as the block type, set the perimeter shape to **1-Polygon** and the [Height](#) to the same height as the rotunda, then draw a conventional vertical extrusion to fit flush to the rotunda. In order to trace round the base of the rotunda, it's probably easier to set the view rotation to 'Plan', click on to the ground plane and press SHIFT to lock the plane before placing the first perimeter point:

When tracing around a perimeter by snapping from end-point to end-point, it can be helpful to switch off the [direction](#) snaps and the [drawing guides](#) to prevent them from interfering with the point snaps. Completing the perimeter:

Click on the outline block to select it and then click on the 'Divide block' tool and make sure that the 'Cutting method' is set to **1-Draw plane** in the Drawing Options data panel. Switch the [protractor](#) on and move the cursor over the end face of the selected block, the surface will highlight to indicate that it's become the active drawing plane. Press the SHIFT key to lock the drawing plane and then locate the cursor 4m from the base of the block using [edge snap](#):

Click to place the beginning of the first cutting plane line, then place the end of the line to intersect the face edge with a pitch angle of 30°:

[Orbit](#) to make the back face of the block visible. Move the mouse cursor over the back face and when it highlights, press the SHIFT key to lock the plane. Place the second cutting plane line to snap to the local X-axis of the back face:

Click to complete the cutting plane. The blocks that will be produced by the cut are displayed in red and green, depending on which side of the cutting plane they lie. At this point, you can choose to cancel the cut by pressing the ESC key or selecting 'Cancel Cut' from the right-click menu.

Click again to complete the cut and then select and delete the block that isn't needed:

Go through a similar process to create the other pitch. You may need to switch off the [drawing guides](#) and [mid-point snap](#) to prevent them from interfering with the [protractor](#) and [edge snap](#):

Click to create the cutting plane:

Click again to make the final cut and then select and delete the block that isn't part of the finished structure:

The outline block can then be selected and converted to a building block:

Select Plane Method

The Select plane method of cutting a block uses an existing plane to define the cutting plane. It can be demonstrated by modelling a roof offshoot:

Click on the [Add new block](#) tool, select [2-Outline block](#) as the [block type](#) and set the [perimeter shape](#) to **1-Polygon**. Switch the [protractor](#) on and move the mouse cursor to the back face of the offshoot. When the cursor is over the back face, press the <Shift> key to lock the drawing plane and snap the protractor to the upper edge end-point:

Draw the first perimeter line at a 45° pitch and move the cursor to intersect with the back face upper edge mid-point drawing guide and click to set the end-point:

Move the cursor to snap to the other end-point of the back face upper edge and then complete the perimeter:

Now drag the outline block face through the main roof block:

Select the offshoot outline block and click on the 'Cut block along plane' tool, making sure that the 'Cutting method' on the 'Drawing options' data panel is set to 'Select plane' and click on the forward facing plane of the main roof block to create a cut in the offshoot block in the plane of the roof:

Click again to finish the cut and then select the section of the offshoot roof block that is not required and delete it:

Select the roof offshoot block and click on the 'Convert selected outline blocks to building blocks' tool to complete the process:

Note: In some circumstances, resulting blocks may not be able to be converted to building blocks due to geometrical limitations. In this case, the block will be displayed in a sepia colour to indicate that it cannot be converted.

Boolean Geometry Operations

DesignBuilder provides some powerful modelling tools for combining blocks in various ways to create new more complex geometric forms. Boolean geometry (otherwise known as [Constructive Solid Geometry](#) or CSG) provides these functions:

- **1-Union**, the most common Boolean tool where 2 or more adjacent blocks are combined into a single new block.
- **2-Intersection**, where a new block is formed where 2 original blocks intersect.
- **3-Subtraction**, in which one block is subtracted from the other to form a single new block.

The Boolean process works in 4 stages:

1. Select the blocks involved. The union operation can be applied to any block type including building blocks, component blocks and outline blocks, whereas the Subtraction and Intersection operations can only be applied to outline blocks as they require intersection of the 2 primary blocks. The blocks must both either be of the same type (building block /component block /outline block) or must involve an outline block. The blocks must touch in the case of the Union operation and intersect in the case of the Subtraction and Intersection operations.
2. Click on the Boolean operations toolbar icon. This opens the Drawing options dialog in the bottom left of the screen.
3. Select the operation type in the Drawing options panel in the bottom left of the screen. When 2 or more building blocks are selected Union is the only option so the drop list is greyed out. The blocks involved are shown in brown/purple for the Union and Intersection operations, or one in brown/purple and the other in green for the Subtraction operation. For the Subtraction operation the green block will be used to subtract space from the purple block.
4. Left-mouse click a final time on the model to complete the operation.

Note: The Boolean tools work most effectively when the geometry has been constructed accurately using snaps to ensure that adjacent blocks are positioned correctly. If the model geometry has issues such as adjacent block vertices being very slightly out of alignment, this can lead to Boolean operations being disallowed in some cases.

See also the [Outline blocks, Boolean operations](#) tutorial

Using the Boolean Operations - Union Blocks Example

The first step in using the Boolean Union tool is to go to building level and select 2 or more blocks to combine.

In this example, 2 blocks are to be combined are shown above. Before the operation is started the model consists of a 3.5 m height L-shaped block adjacent to a tall sports hall block.

When the 2 blocks are both selected the screen looks as above with the **Boolean** operations toolbar icon enabled.

Clicking the **Boolean** toolbar icon starts the command and the Display options panel is displayed in the bottom left of the screen. On this panel there is a drop list with the 3 Boolean functions available for selection.

Note: In the case where 2 building or component blocks are selected, only the Union operation is allowed. This is because building blocks cannot intersect and the Subtraction and Intersection options do not apply as they require blocks to intersect.

Once the command has been started the 2 blocks will be coloured brown/purple. To complete the operation, click once more on the edit screen with the mouse.

After the final click, the 2 blocks are combined into a single block as shown above.

This can be a very useful way to simplify building geometry avoiding use of multiple blocks and easing the creation of zones that may span what were multiple blocks.

Note: When combining adjacent blocks using the Union operation, block boundary walls that used to separate the blocks are not replaced by partitions.

Using the Boolean Operations - Subtraction Example - Nested Glazed Ellipsoids

This example illustrates how to create a complex geometry with one ellipsoid (egg-shaped) block within another.

Step 1 - Draw 4 construction lines starting from origin to create a cross centred on the origin 20 x 10m

Step 2 - Draw a dome 20m radius centred on the origin, then use the Stretch tool to reduce it's y and z dimensions by 50%. The dimensions should be 40m in the x-direction, 20m in the y-direction and 10m height (z-direction).

Step 3 - Draw a similar but 2x smaller ellipsoid 10m x 5m x 5m. Move the large ellipsoid on top of the smaller one with the centre of each over the origin as shown below.

Step 4 - Use the selection tool to rubber band a selection over both blocks, click on the Boolean operations toolbar icon and select the Subtraction option in Drawing options. If necessary click on the Switch subtraction block checkbox to ensure that the smaller inner block is in green (i.e. it is to be used to subtract volume from the larger block). After the Subtraction operation you should see the blocks as below.

... and with the smaller inner block moved out of the way:

Step 5 - Draw a small rectangular outline block aligned with the x and y axes to give you a vertical plane to allow rotation operations to create the lower blocks. Then copy the larger outer block and rotate the copy by 180° using a vertical plane as the rotation plane. Repeat these steps for the smaller inner outline block.

Step 6 - Position and Union the 2 small inner blocks together to create an egg shaped inner block.

Step 7 - Move the inner outline block into place.

Step 8 - Convert the outline blocks to building blocks

Step 9 - Move the lower outer block into position.

Step 10 - If necessary, move the entire set of 4 blocks above ground by selecting all 3 blocks (rubber band selection) and using the base point of the lower outer block as the reference point and moving it the origin.

Step 11 - Set 100% glazing for exterior, interior and roof glazing.

Step 12 - Draw 2 holes in the floor of the outer top block. Note it is not possible to union the 2 outer blocks as there would be problem maintaining the inner blocks in this case.

Step 13 - Visualise and check the geometry is as expected.

Edit Block Options

You can edit certain aspects of a building block geometry by clicking on the Model options icon while at the block level. This opens the Model options dialog box opened on the [Block](#) tab.

See also the [Program and Model Options](#) tutorial

Convert Blocks

To convert one or more blocks to a different [Block type](#) follow the steps below:

1. Navigate to building level.
2. Select the [Outline](#), [Building](#), or [Component](#) block(s) to be converted by clicking with the mouse.
3. Click on the **Convert selected block** toolbar icon to open the **Convert Block Options** dialog as shown below.

4. Select the type of block to convert the selected blocks to. Choose from the options:
 - [Building block](#)
 - [Component block](#)
 - [Outline block](#)
5. Press OK to complete the operation.

See also the [Outline blocks, Boolean operations](#) tutorial

Transfer Blocks

You can move blocks from one building to another using the Transfer blocks command accessed from the [Edit](#) menu when the site contains more than 1 building. This menu option opens the Transfer blocks dialog below. Select the building containing the blocks to be copied and the building to receive the blocks and Press OK. *All blocks* in the source building will be moved to the destination building.

Tip: If you would like to transfer only selected blocks then you could first clone the source building, remove the blocks that are not required from the copy then transfer the remaining blocks to the destination building.

Note: You should check before starting the block transfer that none of the source blocks overlap with blocks in the destination building. Even a small overlap will cause the whole process to fail.

A Transfer block operation cannot be undone and it clears any existing undo/redo information.

Add Surface

The topology of a block can be edited using the **Add surface** tool which allows you to modify a block surface by drawing a perimeter on an existing block surface and dragging it inwards or outwards along an axis, normal to the surface. It is a special case of the [Drag block face](#) tool which is used to drag a whole face. Add surface allows you to drag a portion of a block surface creating a new block topology.

To use the **Add surface** command:

1. Go to the building level (or block level if you wish to add a surface to a block-level component block).
2. Click on the **Add surface** tool.
3. Move the mouse cursor to the surface that you want to edit and draw the perimeter of the surface to be created.
4. Once the new surface perimeter has been defined use the mouse to start dragging it inwards or outwards. You can key in an exact distance to be used in the drag process. See example screenshot below.

5. When you have the block geometry you need, left mouse click to confirm.

See also the [Add surface, increment snaps](#) tutorial

Adding Solar Collectors

To add or create a new Solar collector follow these steps:

1. First go to the building level (if you are not already there) and click on the **Draw solar collector** toolbar icon.

2. Select the type of collector from the pop-up menu. For example to add a PV panel, select the **Add solar collector - Photovoltaic** option.

3. Position and draw the Solar collector in the way that you would a block when using the **2-Rectangle shape**. The first click defines one corner (the bottom right say), the second click defines the diagonally opposite corner (top left say) and completes the placement.

The panel is effectively defined in 2-D, i.e. there is no option to define its depth.

You can draw the panel on an existing building block, component block or outline block surface or directly on the ground.

Note: In cases where a solar collector is placed on a building surface (e.g. on a pitched roof surface) it is not modelled as being thermally coupled with the underlying surface by default, but it does cast a shadow like any other block or shading surface.

PV panels can however be thermally coupled to the building using the BIPV tools, specifically using the [Heat transfer integration mode](#) for the Construction used for a surface below the panel.

4. You can edit the properties of the solar collector by first navigating to the Solar collector object by either double-clicking on the graphical object in the Layout screen or single-clicking on the item in the Navigator. For PV solar collectors you can define the panel performance and other properties on the [Construction tab](#) under the [Solar Collector header](#).

5. The electrical side of the **Photovoltaic** collectors operation is defined on the HVAC tab under the [Generation](#) header.

The hot water, operation and control of **Solar hot water** collectors is defined with the Detailed HVAC data.

Note: PV systems can be modelled when using either Simple or Detailed HVAC but Solar hot water systems require Detailed HVAC.

Panel Active Direction

When placing a solar panel, one face will usually be pointing upwards towards the sky and the other downwards towards the ground or the building. DesignBuilder automatically determines the "active" side as the one pointing upwards. The active face of the panel is displayed in blue for PV panels and in yellow for solar hot water panels, as shown below.

Changing the active direction

In some cases it may be necessary to change the active direction of a solar panel. For example, when the panel is placed vertically, or after it has been rotated to a new slope and the active face is pointing downwards. In such cases you can change the active side of the panel by holding the <Shift> key down and left-clicking with the mouse. This toggles the active face.

Edit Openings At Building Level

Building block façade openings can be selected at the building level and subsequently [moved](#), [copied](#), [mirrored](#), [stretched](#) or [deleted](#).

In order to edit openings at the building level you first need to select the openings, either clicking on them using the [Select](#) tool or by dragging a selection window around them:

The selected openings are highlighted:

When you have selected an opening, you will see that the [Move selected object\(s\)](#), [Clone selected object\(s\)](#), [Mirror selected object\(s\)](#), [Stretch selected object\(s\)](#) and [Delete selected object\(s\)](#) icons are active and you can select one of these commands. As an example, the arched openings and doorway are to be copied onto the angled façade of the leftmost block. To begin with, you need to delete the existing opening on the angled façade by selecting it and clicking on the [Delete selected object\(s\)](#) icon:

Opening removed:

All opening edit operations at the building level automatically convert default openings to custom openings, which is why you need to remove the existing opening.

Then in order to copy the openings, you need to select a **handle point** and you can do this by first clicking on the [Clone selected object\(s\)](#) command icon and then clicking on the required handle point - the [endpoint snap](#) will help in selecting the handle point.

First select the handle point, and then position the copy using the various [snaps](#):

As you move the copied openings across each block façade you will see them automatically snap into the façade plane and after positioning the openings, you can then click on the mouse key to add the openings in the required position:

You will see that any copies that won't fit into the selected location are automatically discarded.

Note: You can select openings on multiple planes, but in this case the openings can only be deleted, not moved or copied.

See also the [Drawing windows and doors](#) tutorial

Working At Block Level

This section describes the various operations involved in [partitioning](#) a block to create zones and adding [courtyards](#) to blocks. Before you start to draw partitions or courtyards, you first need to go to the block that you want to edit and you can do this by clicking on the block entry in the navigator or by double-clicking on the block in the 'Edit' screen, if you're at the building level.

Go to block level

Either of these operations will take you to the block:

At block level you can also:

- Add and edit **1-Standard** type [component blocks](#) for use in visualisation, daylighting and CFD analysis.
- Add internal [CFD fans](#) for CFD analysis.

Block Level Options

When drawing construction lines or using the measure tool at block level, some special options become available in the **Drawing Options** panel.

Snap mode

At block level the **snap mode** allows you to specify whether snaps should be made available for the block outer perimeter or for the zone inner surfaces. The options are:

- **1-Block perimeter** where snaps are provided for the block perimeter lines.
- **2-Zone inner surfaces** where snaps are instead provided for the zone inner surfaces.

Display zone inner surfaces

This option can be found under the **Display** header in the **Drawing Options** panel. When checked it ensures that the zone inner surfaces are displayed in addition to the block perimeter surfaces.

☐ Generic Office Area

Display zone inner surfaces OFF

 Generic Office Area

Display zone inner surfaces ON

By default the option is switched off and the zone inner surfaces are only represented by a dotted line on the floor plane. To get a clearer picture of where all of the zone inner surfaces are, you can switch this option on.

Zone Block By Drawing Partitions

Building blocks can be divided into any number of zones by drawing partitions inside the block. To start drawing partitions, click on the 'Draw partitions' tool. You can place partitions freely within a block either free-standing or snapped to an external block wall or existing partition. Partitions can be positioned using the [snaps, drawing guides and protractor](#). A partition doesn't need to be snapped to a wall element, you can drag a partition across a wall and when you click the end-point, it will be automatically trimmed to the wall.

You can enter the thickness of the first partition drawn in the block and subsequent partitions take on the same thickness as the first.

See also the [Partitioning blocks to create zones](#) tutorial

Note for partitioning large models

By default, blocks are automatically re-zoned as soon as complete zone perimeters are formed by drawing partitions. In order to speed up the process of adding partitions, particularly in the case of large and complex blocks, the block zoning process can be postponed until all partitioning for the current block has been completed. The easiest way to do this is to switch off the **Automatic block zoning** option under the **Display** header in the Drawing Options panel while drawing partitions. You also achieve the same effect by opening the Model options dialog and switching off the **Automatic block zoning** option under the **Miscellaneous Edit** header on the **Drawing Tools** tab. When partitioning has been completed, the block can be manually re-zoned by selecting the **Rezone block** command from the **Tools** menu. Partitions drawn with the **Automatic block zoning** option switched off are called **Outline partitions** and are shown in blue.

Rezoning blocks

When partitions are moved and/or deleted, DesignBuilder attempts to match the new zone geometry with the previous geometry and, if it is successful, it keeps the previous zone attributes. The matching is done based on overlaps with the floor areas of the old and new zone layouts. After partitions have been moved or deleted the software checks for overlaps in floor areas between new zones and previous zones and if overlaps are found, the attributes are inherited from the previous zones. The exception to this is for detailed HVAC zones where the floor area must match exactly for the new zone to be interpreted as a reworking of a previous zone.

Switching off the **Automatic block zoning** option can be a big help when rezoning an existing block layout when aiming to maintain zone and surface attributes from the previous layout because it allows the timing of the matching process to be controlled. For example, in the following simple example, if all partitions are first deleted (with automatic block zoning turned on), the resulting single zone will inherit all attributes from the previous zone with the largest floor area and so any subsequently partitioned zones will inherit from that single zone:

However, if "automatic block zoning" is turned off prior to deleting the partitions and the block is manually rezoned after adding the new partitions, the four new zones will inherit from the original four zones:

Partition Block Into Zones

Click the partition end-point on the outside of the wall and it's automatically trimmed:

When you draw a partition or a series of partitions (stream), you can undo the last point placed by pressing the ESC key or selecting 'Undo last point' from the right-click menu.

You can also terminate a partition stream anywhere by selecting 'End stream' from the right-click menu (or by pressing the ENTER key):

When partitions or partition streams are placed that don't connect with anything at either or both ends, they are called [hanging partitions](#) and can be used to add thermal mass to zones:

Once you've placed partitions that divide existing zones within a block, the block is re-zoned automatically:

When you partition complex blocks rather than simple vertical extrusions, partitions are automatically cut to fit within the block:

Tip: If the display of the block outer walls prevents you from drawing partitions (for example in a pitched roof block) then you can switch off the [display filled external walls](#) model option.

Deleting Partitions

When a partition between 2 zones is deleted, the new zone created from the 2 previous zones will use the attributes from the original zone having the greatest floor area.

Complex Block Geometry

In some cases, if the geometry is complex, it can be possible to create a zone that comprises several geometric bodies which are physically separated from each other. For example, in the case of a horizontally extruded 'C' shape:

If a partition is drawn as shown:

The partition and resulting zone will be cut to form what appears to be two partitions and two zones:

However the two resulting zones are in fact two geometric bodies within one zone:

While this geometry is perfectly acceptable for the default EnergyPlus solar calculations (see Model Options), it cannot be processed by the more rigorous [Full exterior and interior](#) solar distribution option. If this latter option is required, you can either model the geometry as two separate blocks or [cut the block](#).

Hanging And Outline Partitions

Hanging partitions are partitions that do not create zones because they do not connect at both ends with other walls and/or partitions. Hanging partitions are created in the same way as ordinary partitions using the [Draw partition](#) tool, but are finished by pressing <Enter> (or the **End partition stream** command from the right click menu) to define the end of a partition stream. They are shown in light blue (see below) to differentiate them from normal and virtual partitions.

Hanging partitions are modelled non-geometrically in EnergyPlus as [Internal thermal mass](#).

Note: Hanging partitions are not included in visualisation, daylighting and CFD studies (see below). You should use internal component blocks to create an obstruction to daylight, CFD air movement or for more realistic visualisations.

Outline partitions

Also if [Automatic block zoning](#) is switched off, all new partitions are treated as outline partitions (shown in blue and do not create zones) until converted to standard partitions by using the [Rezone block](#) command from the [Tools](#) menu.

Virtual Partitions

A virtual partition is a partition between 2 zones which exists purely to sub-divide the space up and has no corresponding wall in the actual building.

Virtual partitions are commonly used for separating perimeter zones from core zones when there is to be different HVAC provision or when carrying out daylighting or solar overheating studies in situations where a large open plan space is subject to a high level of solar gain around the perimeter. Virtual partitions can be placed to create separate perimeter and core zones so that the local effect of the solar gain in the perimeter zone may be calculated. In the absence of virtual partitions, the risk of overheating could be underestimated due to the distribution of solar gain throughout the open plan space.

When drawing partitions you can set the Partition type in the Drawing option panel to **1-Standard** (the default for a standard partition) or to **2-Virtual** to create a virtual partition.

For partitions that have already been created you can navigate to the partition (click on the appropriate item in the Navigator or double-click on the partition object from either zone or block level) and change the partition type between **1-Standard** and **2-Virtual** using the Partition type Drawing option control. This is only possible for partitions within a block and inter-block partitions cannot have their partition type set to **2-Virtual**.

Note: Virtual partitions are modelled using a hole that fills the whole surface area so you cannot draw custom openings on a virtual partition. For details on how DesignBuilder EnergyPlus models virtual partitions see information on [holes](#). The [model options](#) for controlling the effect of holes apply equally to virtual partitions.

See also:

- [Merge zones connected by holes](#)
- [How airflow through holes \(and virtual partitions\) is modelled](#)
- [Natural ventilation options](#)

See also the [Partitioning blocks to create zones](#) tutorial

Creating Voids (Courtyard Spaces) Within Blocks

To create an external courtyard within a block, go to the required block by clicking on the navigator entry or double-clicking the block and then click on the **Draw void perimeter** tool. You can select a perimeter [shape](#) and the line type used to draw it in the **Drawing Options** data panel:

After completing the perimeter, a courtyard is automatically generated within the block:

Important note: in simulations, the void space is treated as **exterior** to the building and not as any sort of zone. If you need to create an atrium space whose temperature and other conditions are simulated then avoid use of the **Draw void perimeter** tool and instead model it like any other zone within the block using partitions.

If you would like DesignBuilder to automatically punch voids through new blocks drawn on top of existing blocks having voids, then use the [Automatically include voids from lower blocks](#) model option which can be set on the [Miscellaneous Edit](#) tab of the model options dialog.

Restriction: The void perimeter lines you draw to create a void cannot touch any other external or internal wall, so you can't for example use the void command to take chunks out of the external wall - the void must be wholly contained within the block.

Restriction: You can't create any other objects within a void - the void space is reserved and you will get intersection errors if you try to draw a block in the void space. If you need to do this then you should create a "hard" void using [Boolean tools](#) instead (see below).

Soft And Hard Voids

There are 2 ways to create voids, such as courtyards, in DesignBuilder:

- **"Soft" voids** are the courtyards etc added to a building block using the **Draw void perimeter** tool described above. Soft voids are "soft" because they can be moved and generally edited.
- **"Hard" voids** are created by cutting a hole through a block using a **Boolean** operation.

The main practical differences between "soft" and "hard" voids are that:

- another block (building block, component block, solar panel, assembly) can be located within a hard void but this is not possible within a soft void, and,
- soft voids can be edited at block level using the delete, copy, move, rotate, etc. commands.

Open Manifold Blocks - Flip Block Surface Orientation

This command applies only to open manifold blocks imported from BIM models. It can be accessed from the Edit screen when at building level when an open manifold block is selected or when at block level for an open manifold block. Using the **Ctrl-F** keyboard shortcut is the fastest way to start the flip block command.

Open manifold blocks cannot use all geometry operations and the surface orientation cannot be reliably determined from the model. DesignBuilder must rely on the orientation data stored with the surface from the BIM model. This data is not always reliable and so in some cases surfaces come through into DesignBuilder facing in the wrong orientation. The **Flip block surface orientation** command can and should be used to check and, if necessary fix, the orientation of surfaces in all open manifold blocks.

When the Flip Block Surface Orientation command is active you can click on the surfaces in a block to see their orientation. You should see the red arrow pointing **outwards** away from the centre of the block as shown below.

Some surfaces may be facing in the wrong direction (inwards) and will often be seen in white looking from outside the block as shown below.

Clicking on these surfaces shows the arrow pointing inwards. In this case press the **Shift** key while left clicking with the mouse to flip the direction of the surface to make it point outwards. The image below shows the fixed block looks after the Shift mouse click was used to flip the surface orientation.

All such inward facing surfaces must be flipped to ensure an accurate model before using it to run energy simulations. Otherwise inward-facing surfaces will have the wrong orientation in energy simulations.

Note: even when all surfaces in open manifold blocks have been correctly flipped these models cannot be used in Radiance daylighting and CFD calculations which require all blocks to be closed manifold.

CFD Circulation Fans

One or more CFD Circulation Fans (often referred to as CFD fans) can be added at block level to increase air momentum and add/subtract heat during CFD simulations. The supplied flow rates are converted to momentum equation boundary conditions by combining them with the associated cell dimensions.

Example applications are jet fans and desk fans which can both be modelled using the CFD circulation fan to add movement to the air.

CFD Fans are only used for CFD simulations and have no impact on any other calculations.

Add CFD Circulation Fan

The position and size of a CFD fan is defined by drawing a line (typically in the X-Y plane) and extruding to create a rectangular plane. Air will flow through the fan, perpendicular to the fan plane.

To add a CFD fan:

1. Navigate to the block where the fan is to be placed.
2. Click on the **Add CFD circulation fan** toolbar icon.
3. Move the mouse cursor to the starting position of the fan plane and left click with the mouse to start drawing.
4. Move the mouse to the end position of the fan plane and left click again to complete the base line.
5. Now move the mouse perpendicular to the line to extrude creating a plane. Once you have set the required extrusion length, left click to complete the fan geometry.
6. Once the fan has been drawn, you may want to move the fan to final position (e.g. on to a desk) or rotate it etc. The screenshot below shows a fan that has been moved off the ground (using the [Move](#) command with z-snap) and [rotated](#).

Fans can be drawn onto the block floor, onto component or outline blocks or onto walls of the block.

7. Having now drawn (and possibly repositioned) the fan, the final step is to define boundary conditions for any heat flux added by the fan (e.g. fan heater), the flow rate and the direction.
8. Navigate to the fan either by double clicking on the object in the model view or by clicking on the CFD Fan item in the Navigator and click on the [CFD](#) model data tab.
9. Enter any heat flux added by the fan, the fan flow rate and the direction as shown in the screenshot below.

10. To change the direction of flow, change the **Flow direction** setting from **1-Positive** to **2-Negative** or vice-versa.

Note: The fan discharge area dictates the fan discharge velocity and consequently the momentum for a given flow rate.

Working Within Zones (Zone Level)

This section describes the operations involved in placing [light sensors](#) within zones. To [place light sensors](#) within a zone, you first need to go to the zone that you want to modify. You can do this from the block level either by clicking on the navigator entry or double-clicking on the zone floor in the 'Edit' screen if you're at the block level.

Go to zone level

Either of these operations will take you to the zone:

Placing Light Sensors

If you switch zone [Lighting Control](#) on, a light sensor will be displayed as a blue rectangle with the number '1' inside it indicating 'Light sensor 1'. By default Light sensor 1 is positioned in the geometric centre of the zone.

If you now switch on the [Second Lighting Area](#), a second light sensor will be displayed with a number '2' inside it:

To move a light sensor to a different location, move the mouse cursor over the required sensor and click on it to select it and then [Move](#) it to wherever you want within the floor perimeter:

Note: You can set the [working plane height](#) to define the desk height (and hence the z-position of the lighting sensor) on the [Lighting tab](#).

See also the [Lighting data and daylight controls](#) tutorial

Working With Surfaces (Surface Level)

This section describes the operations involved in creating surface openings and sub-surfaces. To [create openings](#) and sub-surfaces in a zone surface, you first need to go to the surface that you want to modify. You can do this from the zone level either by clicking on the navigator entry or double-clicking on the zone surface in the 'Edit' screen, if you're at the zone level.

Go to surface level

Either of these operations will take you to the surface:

Note: When navigating to surfaces from zone level by clicking on them with the mouse, to access the "backward-facing" surfaces (i.e. surfaces whose *inside* face is shown) you must hold the Shift key down while clicking.

When working with surfaces, switching to [Normal view](#) rotation can be helpful in orientating openings and sub-surfaces:

Openings

You can draw, move, clone (copy), rotate and delete the following types of opening:

- [Window](#)
- [Sub-surface](#)
- [Hole](#)
- [Door](#)

- [Vent](#)

Note that custom openings that have been drawn by hand or copied are displayed in bright colours to differentiate them from (grey) default openings:

- Yellow - windows
- Blue - sub-surfaces
- Green - holes
- Cyan - doors
- Magenta - vents

Note: All openings and sub-surfaces in adiabatic surfaces are ignored in EnergyPlus simulations

See also the [Drawing windows and doors](#) tutorial

Surface Polygons Generated for EnergyPlus - Technical Description

EnergyPlus requires all surfaces to be convex and it does not support surfaces with holes. But of course real-world buildings can have surfaces of any shape. So when DesignBuilder encounters a concave surface or a surface with one or more holes (not openings, but an actual hard geometric hole) it must break the DesignBuilder surface down in to 2 or more polygons. The purpose of this technical description is to explain how that is done. With an understanding of the process applied users may be able to find ways to configure their model geometry to minimise the number of polygons DesignBuilder needs to generate to meet EnergyPlus' requirements.

In order to ensure that valid polygons are provided to EnergyPlus, DesignBuilder follows the process below for concave surfaces with windows:

1. Inflates windows to [account for any frames specified](#) and to provide a 1mm margin around the window.
2. Uses the inflated window size to create a parent surface for each window. A similar process is used for other opening types except that doors, vents, sub-surfaces etc do not have frames, so that part of the inflation is not required.
3. Further sub-divides the surface into convex polygons to ensure that all surfaces provided to EnergyPlus are valid.

The screenshot below illustrates an example case of a concave roof surface with many windows:

DesignBuilder breaks this surface/opening configuration down into EnergyPlus polygons as shown below:

Note the rectangular polygons around each window.

Draw Window

Before activating the **Draw window** tool, you are given the option of keeping any default surface openings through a check box in the Display options dialog. If you choose to keep these openings, they will be converted to custom openings and so will not be subsequently affected by any changes to the façade attribute data and must be deleted or edited manually, or [cleared back to default openings](#).

Note: When drawing windows you should draw the whole opening area in the fabric including the space required for the frame. The way that the frame and window areas are provided to EnergyPlus is described in more detail in the "Dimensions (Walls)" on page help topic.

See also the [Drawing windows and doors](#) tutorial

To add a window to a surface, click on the **Draw window** tool. If you have opted to keep the default openings, they will be converted to custom openings:

On the other hand, if you uncheck the **Keep default openings** option, all default openings will be removed. Select the [perimeter shape](#) that you require and then move the mouse cursor to place the window origin. As you move the mouse cursor over the surface, distance guides will be displayed from each of the surface vertices to help in placing the window origin. If the increment snap is switched on, the origin will snap in increments from the vertex that's nearest to the mouse cursor:

Tip: You can lock the window origin to a particular vertex (surface corner) by moving the mouse cursor close to the vertex and pressing the <Shift> key and keeping it pressed until you actually place the window origin. This can be helpful if you want to place a window relative to a vertex at the other end of the surface:

Having placed the window origin, you can then draw the window using the selected perimeter drawing mode, for details of drawing perimeters please refer to the [Perimeters](#) section.

Using Key Ins To Create Openings

You can type in the precise dimensions and offset from the origin of your window using 'Key Ins'. The procedure is:

1. Start the **Draw window** command as described above.
2. Define the window position relative to an origin by first moving the mouse cursor to define the origin (typically the bottom left corner of the surface)

3. Then type in the offset of the window origin (bottom left corner of the window in this example) in the format x y. Note that there is no comma between the x and the y coordinates.

The coordinates that you type in will appear under the **Key In** header in the Drawing Options panel. The convention used when positioning and drawing openings at surface level is that x increases from left to right and y increases from bottom to top. This is true whether viewing the surface from inside or from outside.

4. Then press <Enter> to define the window origin.
5. Next type in the window width followed by a space followed by the window height. Again the coordinates you type in are shown in the Drawing Options panel. In the example below a window is being defined having width 2m and height 1m.

6. Press enter to create the window:

You can use the mouse in conjunction with Key Ins if you prefer. So you could use the mouse to define the window offset from the origin and then use Key Ins to define the window dimensions or vice versa.

Tip: You can also enter negative x and y values when keying in offset and coordinates.

Draw Sub-Surface

For details of using the **Draw sub-surface** tool, please refer to the [Draw window](#) tool.

See the [Sub-Surface Construction](#) topic for information on the construction data used for sub-surfaces and other details.

Draw Door

For details of using the **Draw door** tool, please refer to the [Draw window](#) tool.

Note: In EnergyPlus doors must be rectangular

See also the [Drawing windows and doors](#) tutorial

Draw Hole

For details of using the **Draw hole** tool, please refer to the [Draw window](#) tool.

Holes are usually used for two purposes:

1. For merging zones together. Note that the [Merge zones connected by holes](#) option must be selected for this to work.
2. If adjacent zones aren't merged then holes between them allow air and radiation to pass. See below for details on this.

Holes can also be added in exterior surfaces to allow air and radiation to pass.

Tip: It is possible to draw large holes in surfaces to give the effect of the surface having being removed. This can be a useful technique for creating atrium-type spaces, connecting gable roof blocks to the main roof block and generally merging zones in different blocks.

More information on Drawing holes can be found in the [Drawing holes and merging zones](#) tutorial

The way holes are modelled in EnergyPlus depends on the model options selected:

Airflow

The way that airflow through holes (and virtual partitions) is modelled depends on the [Natural ventilation](#) model option selection. The rules are as follows.

Scheduled Natural Ventilation and Heating and Cooling design calculations	Simulations with Calculated Natural Ventilation
When the Advanced Natural Ventilation Model airflow through openings and Airflow through internal openings model options are checked, holes positioned on internal partition walls are used to mix the air between the two adjacent zones. In this case the airflow through internal holes is calculated based on the Airflow rate per opening area data. External holes have no effect on airflow. This is because scheduled natural ventilation has no way to calculate the airflow through an external hole which would in reality require knowledge of wind speed and direction and other pressure-related data.	Holes are represented using an unobstructed air flow path in the fabric and air flow through them is unaffected by whether natural ventilation is enabled on the HVAC tab and the natural ventilation setpoints and other controls. The airflow through holes is calculated (using the EnergyPlus Airflow Network) based on the pressure difference across the opening and a coefficient of discharge of 0.65.

Radiation and conduction heat transfer

The way that radiation and conduction of heat through holes (and virtual partitions) is modelled depends on the [solar distribution](#) setting, the [solution algorithm](#) and the calculation type as described below.

All exterior holes and when Solar distribution algorithm is Full interior and exterior	Internal holes in simulations when using CTF solution algorithm	Internal holes in heating design and cooling design or when using Finite difference solution algorithm
Modelled as "windows" with "perfectly clear" glazing and so they transmit solar radiation and conduct heat. Note that in this case the conductance U-value for this special type of glazing is 3.12 W/m ² K.	Modelled as Infrared Transparent surfaces in EnergyPlus. The hole will participate in the transfer of visible and solar radiation by doing a "wavelength transformation", making all short wave length radiation that is incident on the surface into long wave length radiation and having it participate in the long wavelength radiant exchange.	Modelled as an opaque sub-surfaces with a standard "Holes and vents" construction, so no radiation transfer takes place between the 2 zones, only conduction plus any airflow.

Draw Vent

For details of using the **Draw vent** tool, please refer to the [Draw window](#) tool.

Add CFD Boundary

When at surface level you can add a CFD boundary in much the same way as a window or any other opening. Please refer to the instructions for the [Draw window](#) tool for details on the process of drawing the CFD boundary.

Note: An important difference with placing CFD supply and extract boundaries compared with other openings such as windows, is that their edges must not coincide with parent surface edges. The CFD boundary should be separated from the surface edges by a distance of at least 0.1 m.

You should also ensure that there are at least three grid cells between a supply boundary and an obstruction (such as a wall, component or assembly), otherwise, during simulation, the flow can 'lock' and the mass residual will not converge.

After selecting the **Add CFD boundary** tool, the boundary settings are displayed on the Drawing options data panel. You can select the required boundary type from the **Boundary type** drop list. The following boundary types are available for surfaces of all orientations:

- **1-Supply** (general purpose HVAC supply diffuser)
- **4-Extract** (HVAC extract grille)
- **5-Temperature** (surface temperature patch). the heat transfer is calculated in one of two ways depending on the [Surface heat transfer](#) option on the CFD Calculation options dialog selected. If option **2-User defined** is selected, the heat transfer is calculated by combining the specified surface transfer coefficient with the cell surface area and the delta T between the surface and the adjacent cell. If the [Surface heat transfer](#) option is set to **1-Calculated**, the surface heat transfer coefficient is calculated using a wall function.

- **6–Flux** (surface heat flux patch) - the calculation scheme incorporates this flux directly within the cells adjacent to the surface at which the flux is specified. The heat flux is incorporated after multiplying it by the surface area of the cell.

The following additional boundary types for multi-directional diffusers are available for ceiling and other downward-facing surfaces only:

- **2–Four-way** (four-way supply diffuser)
- **3–Two-way** (two-way supply diffuser)

Various settings are available depending on the boundary type:

1-Supply:

- **Boundary temperature** - the temperature of the air entering the space.
- **Flow rate** - the supply volume flow rate.
- **X-discharge angle (°)** - the discharge angle between the local surface X-axis and an inward facing normal to the surface. At the surface level, taking a normal view from the inside of the zone to the surface, the X-axis discharge angle is positive between the normal and the positive X-axis (i.e. the axis pointing towards the right) and negative between the normal and the negative X-axis (i.e. the axis pointing towards the left). For example to define a discharge angle of 45° pointing towards the left of the centre of a diffuser, looking at it from the inside of the zone, you would enter –45. On the other hand, to define a discharge angle of 45° pointing towards the right of the centre, you would enter 45:

- **Y-discharge angle (°)** - the discharge angle between the local surface Y-axis and an inward facing normal to the surface. At the surface level, taking a normal view from the inside of the zone to the surface, the Y-axis discharge angle is positive between the normal and the positive Y-axis (i.e. the axis pointing upwards) and negative between the normal and the negative Y-axis (i.e. the axis pointing downwards). For example to define a discharge angle of 45° pointing downwards from the centre of a diffuser, looking at it from the inside of the zone, you would enter –45. On the other hand, to define a discharge angle of 45°, pointing upwards from the centre, you would enter 45:

- **Min discharge velocity** is the minimum required velocity at the face of the diffuser. The minimum discharge velocity is an important setting in that the diffuser supply velocity in conjunction with the diffuser discharge angle(s) can determine the flow pattern in a space.

The following paragraph only applies to orthogonal diffusers only. If the minimum discharge velocity cannot be achieved by combining the specified flow rate with the face area of the diffuser as drawn, supply diffusers are created using a number of elements, the areas of which are determined by combining the specified volume flow rate together with the minimum discharge velocity. The maximum linear dimension of each component element is currently 'hard-set' at 0.2m. If the minimum discharge velocity is set to a very small value (e.g. 0.01m/s), a single element will be created spanning the entire area of the diffuser as drawn and the actual discharge velocity will be determined from the geometry of the diffuser face and the supply volume (i.e. $v=V/A$). The actual discharge velocity is displayed for diffusers on the CFD data tab at the opening level.

Note: In the case of **non-orthogonal** supply diffusers, the minimum discharge velocity can only be guaranteed if the diffuser has no tilt in the z-dimension (i.e. it has a non-orthogonal azimuth but zero tilt).

Note: Supply diffuser discharge angles only apply to orthogonal diffusers, i.e. to diffusers aligned with the grid. For diffusers placed on non-orthogonal diffusers the discharge angles simulated will be incorrect.

2-Four-way

- **Boundary temperature** - temperature of the air entering the space.
- **Flow rate** - the supply flow rate.
- **Multi-way diffuser discharge angle (°)** - the discharge angle is the angle between the downward pointing normal and the diffuser jet.
- **Minimum discharge velocity** - the minimum required velocity at the face of the diffuser. Four-way diffusers are created using four separate elements, one located at each edge of the diffuser, the area

of each being determined by combining the specified volume flow rate together with the minimum discharge velocity.

3–Two-way

- **Boundary temperature** - the temperature of the air entering the space.
- **Flow rate** - enter the supply flow rate.
- **Multi-way diffuser discharge angle (°)** - the angle between the downward pointing normal and the diffuser jet (see illustration in 'Four-way' section).
- **2-way diffuser discharge direction** - the local surface axis along which the diffuser is to discharge.
- **Minimum discharge velocity** - the minimum required velocity at the face of the diffuser. Two-way diffusers are created using two separate elements, one on either side of the diffuser along the discharge axis, the area of each being determined by combining the specified volume flow rate together with the minimum discharge velocity.

4–Extract

- **Flow rate** - the extract flow rate.

5–Temperature

- **Boundary temperature** - temperature for the patch.

6– Flux

- **Heat flux** - heat flux for the patch.

Note: You can add all types of CFD boundary conditions to zone surfaces, but only supply and extract CFD boundaries can be added to component block surfaces.

Edit Surfaces

At the surface level, you can select custom openings and [move](#), [clone](#) (copy), [delete](#) and [rotate](#) them.

Note: Default openings cannot be selected and manipulated in this way.

You can also clear custom openings their default state using the [Clear Data to Default](#) command.

Undo/Redo

Undo/Redo commands accessed from [Edit](#) menu

To undo a geometric operation, select Undo from the 'Edit' menu (or press <Control-Z>) and similarly to redo a geometric operation, select Redo (or press <Control-R>). Because many of the geometric operations are dependent on specific model levels, you may need to undo or redo navigation operations before you get to the required geometric operation, e.g. 'Undo - Go to surface', etc.

Note that Undo/Redo applies only to geometric operations and *changes to Model Data cannot be undone*.

Rebuild

Rebuild command accessed from [Tools](#) menu

Sometimes the adjacencies within DesignBuilder models can become corrupt. The **Rebuild** command recalculates the zone, surface and adjacency geometry from the base building elements.

See also the [Setting adjacency conditions using ground and adiabatic blocks](#) tutorial

Rezone Block

Rezone block command accessed from [Tools](#) menu

Use the Rezone block command to refresh the zoning in the current block. The command converts any [outline](#) partitions in a block to standard partitions and updates zones due to any partitions that may have deleted. The command should be used when the Automatic block zoning model option is switched off. When the option is switched on (and it has always been switched on during the life of a model) then you will not need to use this command.

Model Data

Model Data is the data for the [site](#) on the tabs:

- [Location](#)
- [Legislative region and insulation standards](#)

and data for [building model](#) on the tabs:

- [Activity \(usage\)](#)
- [Constructions](#)
- [Openings](#) (windows, doors, vents, holes, sub-surfaces)
- [Lighting](#)
- [HVAC](#)
- "On Site Electricity Generation" on page 523 (on site electricity generation)
- "Economics" on page 548
- "Miscellaneous" on page 638
- "CFD" on page 642

The Model Data tabs are shown in the [Edit Screen - User Interface](#) help topic.

At the point of the building is created, building model default data is initially loaded at the building level from templates. This is inherited from the building to blocks to zones to surfaces and to openings. This default model data can be overwritten by making edits on the Model Data tabs on the [Edit screen](#).

See the [DesignBuilder User Interface – Model Data: Site level, model data tabs, data hierarchy and inheritance](#) tutorial

Site Data

The **site data** represents information about the site including its location, the conditions of the ground, weather, the legislative region and the maximum allowed U-values for new buildings. All buildings on the site use the same site model data.

To edit site model data, go to site level and click on the Location or Region tabs (below).

You can easily change the location of the site by making a selection for the [Location template](#) on the [Location tab](#) or by using the [Load data from template](#) command.

Alternatively you can open up the headers on the [Location](#) and [Region](#) tabs to edit the data.

See also the [Site level data and weather files](#) tutorial

Location

Location tab on model data at [Site level](#)

Use this screen to edit the location of the site, its weather data, the daylight savings and energy codes which apply.

You can load a location from the database by clicking on Template line under the Location Template header then on the '...' at the right of the line.

Select location template

When you make a selection from the list of [location templates](#) data from selected template will be loaded to the model.

Alternatively you can use the [Load data from template](#) tool.

You can enter data on:

- [Site location](#),
- [Site details](#),
- [Time and daylight saving](#),
- [Simulation weather data](#),
- [Winter design weather](#) and
- [Summer design weather](#).

See also the [Site level data and weather files](#) tutorial

Site Location

[Location tab](#) on model data at [Site level](#)

You can set the latitude/longitude of the site for cooling design calculations as well as a number of site characteristics.

Latitude

The latitude (in degrees) of the site. By convention, North Latitude is represented as positive; South Latitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

Longitude

The longitude (in degrees) of the site. By convention, East Longitude is represented as positive; West Longitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25).

Note: the latitude, longitude and time zone location data will only affect cooling design and Radiance illuminance calculations. For EnergyPlus and annual Daylighting simulations, the position of the sun is defined by the data in the [hourly weather file](#) header.

ASHRAE Climate Zone

The climate zone as defined by ASHRAE and loaded from the Location template can be overridden by selecting from this dropdown list This allows you to deal with situations where the default climate zone does not agree with the value in ASHRAE 90.1 Standard Appendix D. This is an important setting for ASHRAE 90.1 models as it defines the baseline constructions, glazing etc. to be used for the building.

See also the [Site level data and weather files](#) tutorial

Site Details

- "Site Details - General" on page 290
- "Site Details - Site Height Variation" on page 292
- "Site Details - Ground" on page 293
- "Horizon" on page 313
- "Site Details - Mains Water Temperature" on page 313
- "Site Details - Precipitation + Irrigation" on page 314
- "Site Details - Outdoor Air CO2 and Contaminants" on page 316

See also the [Site level data and weather files](#) tutorial

Site Details - General

[Location tab](#) on model data at [Site level](#)

Elevation above sea level

This data defines the elevation of the site relative to sea level (in m or ft) and is passed directly to EnergyPlus for use in pressure-related calculations. It is also used to calculate [air density](#) within DesignBuilder when calculating volumetric flow rates from cooling loads.

Site orientation

The site orientation is the angle of the site plan view relative to North. For example enter 45 to rotate the building(s) clockwise by 45° relative to North (screenshot example below). This is the quickest and most reliable way to rotate all the buildings on the site relative to North and allows you to keep your x and y axes aligned with the building.

North is indicated by the direction of the North arrow in the sketch plan view (above).

Warning: While it is also possible to rotate building geometry using the [Rotate selected objects](#) command, once this has been done it is more difficult to make further geometric edits because, for rotations other than 90, 180 or 270°, the x and y axes will be out of alignment with the building. Also, whole-model rotations increase the risk of geometric issues in the model. You are therefore strongly advised to use the **Site orientation** setting instead.

Tip: You can navigate to building level and use the [Measure](#) tool to measure the angle between 2 lines on a floor plan to calculate the Site orientation.

Implementation Details

The **Site orientation** defined here is accounted for in the EnergyPlus IDF input data by rotating the geometry of all site and building objects. Because DesignBuilder handles all rotation itself, it is possible for it to accurately apply additional *building* rotations in combination with the *site* rotation entered here. Building rotations are applied to all building objects (not site objects) about the geometric centre of the building in the x-y plane.

Building rotation applies to a) LEED baseline auto-rotation and b) parametric analysis, optimisation, uncertainty and sensitivity analysis when the [Building rotation](#) variable is selected.

Exposure to wind

The site's terrain affects how the wind hits the building – as does the building height. In addition, the external conduction method usually has its own parameters for the calculation. The options available are:

- **1-Sheltered** - maps to the EnergyPlus "City " setting for towns, city outskirts and the centre of large cities.
- **2-Normal** - maps to the EnergyPlus "Suburbs" setting for "rough, wooded country, suburbs".
- **3-Exposed** - maps to the EnergyPlus "Country" setting for "flat, open country"

When the [Calculated](#) Natural ventilation option is set, the exposure to wind model data affects the [pressure coefficients](#) used . It also affects the calculation of U-values (though these are not used in EnergyPlus simulations).

When the [Scheduled](#) Natural ventilation option is set, the exposure to wind model data affects infiltration when using one of the options normalised to exposed façade area, i.e. **2-m3/h-m2 at 50 Pa** and **3-m3/h-m2 at 4 Pa**. It acts through the **wind exposure class** as explained in the Technical notes under [Infiltration rate](#).

Important note: When the wind exposure setting is changed, the outside convective heat transfer coefficient, outside surface resistance and U-value for each user-defined construction in the [Constructions](#) database is recalculated because the wind exposure affects these values. This is necessary to ensure that the info panel data remains up to date and for local calculations such as SBEM which rely on U-values being up to date.

Site Details - Site Height Variation

[Location tab](#) on model data at [Site level](#)

The Site height variation data is used to specify the local variation in atmospheric properties at the site and should be used only if you require advanced control over the height-dependent variations for wind speed and temperature. The coefficients set here are used by EnergyPlus to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The local outdoor air temperature and wind speed are calculated separately for all zones and surfaces, and optionally for outdoor air nodes for which a height has been specified. With the default inputs, wind speed falls significantly at heights lower than the weather station measurement height, and temperature increases slightly. The algorithms for this calculation are in the Engineering Reference. There are necessary correlations between the entries for this object and the [Exposure to wind](#) setting.

Atmospheric Variables at Two Different Heights Above Ground Level.

Variable	1.5 m	284 m	Absolute Diff	Percent Diff
Air Temperature	15°C	13.15°C	1.85°C	12.3%
Barometric Pressure	101,325 Pa	97,960 Pa	3,365 Pa	3.3%
Wind Speed	2.46 m/s	7.75 m/s	5.29 m/s	215%

Note that using this object overrides the wind speed profile coefficients implied by the Terrain field of the Building object. The wind speed profile coefficients can be estimated from the table above (see Site:WeatherStation) or calculated beforehand using more sophisticated techniques such as CFD modeling of the site terrain.

Use site height variation

Check this checkbox to apply custom variation in atmospheric properties at the site.

Wind speed profile exponent

The wind speed profile exponent for the terrain surrounding the site. The exponent can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the Terrain field of the Building object.

Wind speed profile boundary layer thickness

The wind speed profile boundary layer thickness (in m or ft) for the terrain surrounding the site. The boundary layer can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the Terrain field of the Building object even if this field is left blank. This field can be set to zero to turn off all wind dependence on height.

Air temperature gradient coefficient

The air temperature gradient coefficient (in K/m or °F/ft) is a research option that allows the variation in outdoor air temperature to be defined as a function of height above ground. The real physical value is 0.0065 K/m. This field can be set to zero to turn off all temperature dependence on height.

Site Details - Ground

[Location tab](#) on model data at [Site level](#)

Ground Modelling

Ground modelling method

DesignBuilder provides 4 different ways to model the heat transfer between the ground, the external environment and the building. Select the method to be used from the options below.

- **1-Standard** the default method where a set of 12 fixed [Ground monthly temperatures](#) are used to define the temperature on the outside boundary of building ground adjacent surfaces. Conceptually this is the simplest method since it is based on 1-D ground heat transfer, however it requires prior knowledge of the ground temperature just below the building for accurate calculations of the heat transfer between the ground and the building. Because these temperatures are rarely known in practice, this method can give rise to significant errors and it is not recommended in cases where accurate ground modelling is required.
- **2-Kiva Basic** where a single [Kiva foundation](#) object is used to represent heat transfer to, from and within the ground. This option is ideal for accurate simulations of smaller buildings such as dwellings where a single Kiva foundation object can realistically be used to represent the ground and the connection with the building. It requires only a small amount of extra data entry compared with the **1-Standard** option to define the ground properties etc, but in return it provides a significant improvement in ground modelling accuracy. See below for more details.
- **3-Ground domain** a more detailed method than the previous 2 options where EnergyPlus [ground domain](#) objects are used to represent the ground, basement and foundation configuration and adjacency to the building. See below for more details.
- **4-Kiva Full** the most accurate and flexible ground modelling option where EnergyPlus' Kiva system is used to perform two-dimensional finite difference heat transfer calculations to, from and within the ground. See below for more details on this option.

Note: For heating and cooling design calculations, the **1-Standard** method is always used regardless of the Ground modelling method selected.

Standard Method

This is the default method. You can find detailed information on how to use the **1-Standard** ground modelling method in the "Ground Modelling - Standard Method" on page 298 section.

Kiva Basic Method

Kiva enables detailed modelling of the ground while requiring a minimal amount of data to be entered. The **Kiva Basic** option provides an easy introduction to Kiva ground simulations and is ideal for modelling smaller buildings where a single [Kiva foundation](#) object can realistically be used to represent the ground, foundations, insulation and its adjacencies to the building. Note that the Ground monthly temperatures, Ground deep temperatures, Shallow and Deep ground temperatures described below are not used in Kiva simulations.

When the **2-Kiva Basic** Ground modelling method option is selected, 2 more items are revealed below: **Kiva foundation settings** and **Kiva foundation**. These are the only additional settings that needs to be entered to define the ground modelling, adjacencies etc.

DesignBuilder automatically calculates the fraction of floor perimeters that are exposed to outside based on the model surface adjacencies.

Note: This option is exactly equivalent to the **4-Kiva Full** option when the [Kiva adjacency](#) checkbox is checked at building level and the [Kiva foundation](#) selected at building level with no further overriding settings made at block, zone and surface levels.

Kiva foundation settings

Select a [Kiva foundation settings](#) component that defines the soil thermal and surface properties, the extent of the domain and some calculation options.

Kiva foundation

Select a single [Kiva foundation](#) object to define the extent and properties of any insulation and details of the walls and footings.

Note: These settings are automatically applied to *all* ground adjacent surfaces in the model when using the **2-Kiva Basic** ground modelling method.

Ground Domain Method

The EnergyPlus Ground domain system provides a relatively quick and easy way to access the advanced ground modelling capabilities of the Slab and Basement preprocessor tools which in older versions of EnergyPlus had to be run as external utilities with a manual process required to feed the outputs from the preprocessors as inputs to EnergyPlus. See the [EnergyPlus Auxiliary Programs](#) help for more information on these legacy utilities.

The way that the temperature boundary conditions for the simulations are handled is defined on the [Ground Undisturbed Temperatures](#) tab of the Ground domain dialog. Calculations are based on the hourly weather data and soil properties. Note that the Ground monthly temperatures, Ground deep temperatures, Shallow and Deep ground temperatures described below are not used in Ground domain simulations.

Select the **3-Ground domain** option to activate the ground domain model. This reveals an option to select the number of ground domain objects to use in the study. The number entered here will enable the display of that number of ground domain objects as shown below.

Ground Modelling	
Ground modelling mechanism	3-Ground domain
Number of ground domains	1
Ground domain 1	Default Slab

You will normally need to create new [Ground domain objects](#) to define the exact situation for your model.

Note: Ground domains are not used in any heating and cooling design calculations. In this case surfaces adjacent to ground and [assigned with ground domain objects](#) use the [Ground monthly temperatures](#) as the other side.

Note: You must connect the ground domains defined and selected here to ground adjacent surfaces to complete the domain definition. Wall surfaces that are underground can be selected as basements and any floor that has any ground contact can be defined as having either slab or basement contact.

Tip: Domain-surface connection settings can be made at any of building, block, zone and surface levels. Setting data at building, block or zone level provides a quick way to associate multiple ground adjacent surfaces to a ground domain.

Kiva Full Method

Kiva enables detailed modelling of the ground while requiring a minimal amount of data to be entered. The **Kiva Full** option provides access to the full EnergyPlus Kiva ground capability which allows accurate simulations of the ground, foundations, insulation and its adjacencies to the building. It is an improvement on the ground domain method in terms of accuracy, flexibility and execution speed. Note that the Ground monthly temperatures, Ground deep temperatures, Shallow and Deep temperatures described below are not used in Kiva simulations.

DesignBuilder automatically calculates the fraction of floor perimeters that are exposed to outside based on the model surface adjacencies.

When the **4-Kiva Full** Ground modelling method option is selected, the [Kiva foundation settings](#) must also be selected here at site level. Also each ground-adjacent surface has an option to allow it to be selected as having an adjacency with a [Kiva foundation](#). You should normally check the option and select the appropriate Kiva foundation.

Kiva foundation settings

Select the [Kiva foundation settings](#) component that defines the soil thermal and surface properties, the extent of the domain and some calculation options.

Surface

Ground texture

Select the texture to be used to represent the ground in the rendered view on the [Visualisation](#) screen.

Surface solar and visible reflectance

This is a decimal number between 0.0 and 1.0 and is used to characterize the average reflectivity of the ground throughout the year. Ground reflectance data is used to calculate the ground reflected solar radiation. This fractional amount is used in the following equation:

$$\text{GroundReflectedSolar} = (\text{BeamSolar} \times \text{COS}(\text{SunZenithAngle}) + \text{DiffuseSolar}) \times \text{GroundReflectance}$$

Reproduced from the [IBPSA BEM Book](#).

Important Note: Reflection from the ground is always calculated even if the [Model all external reflections and shading of ground reflected solar](#) option is not selected, in which case the ground plane is considered unobstructed, i.e., the shadowing of the ground by the building itself or by component blocks is ignored. In other words, shadowing of ground-reflected radiation by obstructions such as the building itself and component blocks is only taken into account if the [Model all external reflections and shading of ground reflected solar](#) option is set.

The ground surface reflectance is also used to quantify the reflection of visible light in the [Daylighting](#) calculations.

Some typical ground reflectance values are shown for various surface types below.

Surface Type	Surface Reflectance
Water (large angle of incidences)	0.07
Coniferous forest (winter)	0.07
Bituminous and gravel roof	0.13
Dry bare ground	0.20
Weathered concrete	0.22
Green grass	0.26
Dry grassland	0.2 to 0.3
Desert sand	0.4
Light building surfaces	0.6

Ground Reflectance of Foreground Surfaces from ASHRAE 2009 HOF, Source: Adapted from Thevenard and Haddad (2006).

The default ground reflectance is 0.2.

Snow reflected solar modifier

A number between 0.0 and 10.0 which is used to modify the basic ground surface reflectance when snow is on the ground. Note that the value of $\text{GroundReflectance}_{\text{Used}}$ (below) must be ≤ 1 .

$$\text{GroundReflectance}_{\text{Used}} = \text{GroundReflectance} \times \text{Modifier}_{\text{Snow}}$$

During simulations, the ground is considered to be snow-covered when the SnowDepth data in the hourly weather file is > 0 .

From the IBPSA BEM Book:

Site exposure	Reflectance of snow-covered ground
Typical city centre	0.2
Typical urban site	0.4
Typical rural site	0.5
Isolated rural site	0.7

The default modifier is 2 for both solar and daylight radiation, giving an overall default reflectance for snow covered ground of $0.2 \times 2 = 0.4$, suitable for a typical urban site.

Snow reflected daylight modifier

A number between 0.0 and 10.0 which is used to modify the basic ground surface reflectance when snow is on the ground. Note that the value of `DaylightingGroundReflectanceUsed` (below) must be ≤ 1 .

$$\text{DaylightingGroundReflectance}_{\text{Used}} = \text{GroundReflectance} \times \text{Modifier}_{\text{Snow}}$$

During simulations, the ground is considered to be snow-covered when the `SnowDepth` data in the hourly weather file is > 0 .

Ground Monthly Temperatures

There are 12 fields allowing you to represent the mean ground temperature for each month of the year. These temperatures are used as the outside surface temperature for surfaces [adjacent to ground](#).

Note that the depth at which these temperatures apply depends on the thickness of the ground construction (see above) added to the main floor/wall construction.

Caution: It is generally not appropriate to use the "undisturbed" ground temperatures calculated by the weather converter and provided in the header of EnergyPlus hourly weather files as these values are too extreme for the soil under typical conditioned buildings. A reasonable default value of **2°C less than the average monthly indoor building temperature** is appropriate for large buildings. For smaller buildings, the ground temperatures will be somewhere between that value and undisturbed ground temperatures.

More information about determining appropriate ground temperatures is given in [Ground Modelling](#) and in the EnergyPlus Auxiliary Programs document.

Ground Deep Temperatures

There are 12 fields allowing you to represent the undisturbed deep ground temperature for each month of the year. These temperatures are used when the **1-Deep** [Reference ground temperature](#) option is used in a **15-Follow ground temperature** Setpoint manager.

Tip: Undisturbed deep ground temperatures can usually be obtained from the [epw weather file header](#).

Ground Shallow Temperatures

There are 12 fields allowing you to represent the undisturbed shallow ground temperature for each month of the year. These temperatures are used when the **2-Shallow** [Reference ground temperature](#) option is used in a **15-Follow ground temperature** Setpoint manager.

Tip: Undisturbed shallow ground temperatures can usually be obtained from the [epw weather file header](#).

FCFactor Ground Temperatures

Building energy code and standards like ASHRAE 90.1, 90.2 and California Title 24 require the underground wall constructions and slabs-on-grade or underground floors not to exceed certain maximum values of [C-factor and F-factor](#), which do not specify detailed layer-by-layer materials for the constructions. If using the normal layer by layer definition method for ground constructions, users would need to create a pseudo wall or floor construction to match the thermal performance such as thermal mass effect and U-factor, and rely on the EnergyPlus Basement and Slabs tools to generate the monthly ground temperatures.

A simplified approach has therefore been provided to create equivalent constructions and model the ground heat transfer through underground walls and ground floors for the building energy code compliance calculations. The approach is to create constructions based on the user defined C or F factor with two layers: one concrete layer (0.15 m thick) with thermal mass, and one fictitious insulation layer with no thermal mass. This is all done internally within EnergyPlus and the user simply needs to define C-factor or F-factor values.

There are 2 ways to define the ground temperatures to be used with F-factor and C-factor calculations which are defined through making one of the settings for the FCFactorMethod ground temperature source:

- **1-Hourly weather file** where the monthly values of ground temperature come from the header of the selected .epw hourly weather file. Note if this option is selected then the header in the selected epw file must include at least one set of monthly ground temperatures. DesignBuilder will read the first set of ground temperatures provided in the header which by convention is the closest to the surface.
- **2-Model data** in which case the 12 monthly temperatures are defined below.

Ground Modelling - Standard Method

How It Works

When using the simplest **1-Standard** ground modelling method, heat is transferred between zones and the ground through one-dimensional ground floor surface elements. The 2-D and 3-D effects in the ground heat conduction that occur in reality are not treated by default. EnergyPlus uses ground construction data to model the storage of heat in the ground and it can accurately model heat transfer processes over several days (so it can model the effect of say a warm week followed by a cool week) but it cannot directly model long-term ground thermal storage effects (periods measured in months).

Tip: [Other more advanced methods](#) are also provided for more accurate 2D/3D ground modelling.

EnergyPlus applies a [constant temperature boundary condition](#) for each month on the lower surfaces of ground adjacent elements.

There are 3 ways to create an adjacency to ground in DesignBuilder:

1. Using DesignBuilder's [Auto adjacency detection](#) where ground adjacency is set for all surfaces at or below ground level. By default, all external surfaces which are at or below ground level are considered to be [adjacent to ground](#). For surfaces that are partially above and partially below ground level ($z=0$), only the parts that are below $z=0$ are modelled with ground adjacency.
2. Using [Ground component blocks](#) - any surfaces (or part of surfaces) touching a ground component block are considered to be adjacent to ground.
3. Using the [Adjacency](#) model data on the Construction tab at block, zone and surface levels where external surfaces can be defined as being adjacent to ground by changing the Adjacency model data on the [Construction tab](#) from **1-Auto** to **3-Adjacent to Ground**. If a surface is below ground level but is not adjacent to ground you can select **2-Not adjacent to ground**.

Ground Temperatures

Monthly [ground temperatures](#) are defined at the site level under [Site details](#).

Modellers generally prefer to define the ground temperature just below the slab and exclude the earth layers from the model. This has the advantage of simplicity and clarity and is the approach recommended by EnergyPlus developers.

A contributing factor is that EnergyPlus cannot model very thick constructions so it is necessary to use less thick constructions (2m or smaller) combined with some assumptions about temperatures at about half a metre or less below the floor.

Note: You should not use the ground temperatures in the [EnergyPlus weather file header](#) because these are for undisturbed sites. The temperature beneath buildings is significantly affected by the building itself. The EnergyPlus documentation recommends using ground temperatures of 2°C below average internal temperatures for large commercial buildings (where perimeter heat loss is relatively less important). *Note that this temperature should be applied directly below the slab and should not include ground material.*

Example Application - Basement Or Cellar Under Inclined Ground Slope

This example illustrates how to create a simple 3 storey rectangular building model with:

- Basement which is fully below ground and
- Ground floor is partially buried under an inclined ground plane.

Step 1

Draw 3 blocks on the $z=0$ ground plane. The lowest block will be the basement (completely buried), the middle block will be the ground level block, partially buried and the top block will be the second level. So far only the bottom surface is adjacent to ground because it sits on the $z=0$ plane.

Step 2

Draw 2 ground component blocks around the basement building block to give it's surfaces ground adjacency.

Note this step could be avoided by moving the whole building down so that the basement is fully below ground. To do this go to building level, select all the blocks, select the move command, click on one of the bottom corners of the middle block to create a reference point then click on a blank part of the screen to move the reference point down to $z=0$.

Step 3

Draw three new [ground component blocks](#) to create the sloping ground and the upper ground levels.

Step 4

The zone of the middle block is shown above. Notice how 3 of the surfaces have been split into external and ground adjacencies (ground adjacencies are flagged by green ground symbols). Note also that the portions of the surfaces touching the ground component block cannot have windows but DesignBuilder attempts to set up the correct % glazing for the remaining external parts of the surface.

Step 5

The ground component blocks probably do not need to shade this model as they are mainly below all surfaces that can receive solar radiation/light, but if you are modelling reflections you will probably need to include the reflection of solar radiation and light from the ground blocks during simulations. In other cases you may prefer to switch off the generation of the component blocks shading/reflection surfaces to speed simulations. Do this on the Constructions model data tab under [Component Block](#).

Step 6

The finished model. The texture of Ground component blocks is defined by the [material](#) set under Component blocks on the Constructions tab.

Kiva Summary

This summary applies when the [Ground modelling method](#) has been set to **2-Kiva Basic** or **4-Kiva Full**.

[Kiva™](#) is an open source foundation heat transfer calculation tool developed by Big Ladder Software. It is the product of research by Neal Kruis where he proved that accurate foundation heat transfer calculations can be performed quickly without any noticeable loss of accuracy relative to a mesh-independent, fully three-dimensional simulation.

Within EnergyPlus, Kiva is used to perform a set of two-dimensional finite difference heat transfer calculations. Each [Kiva foundation](#) is represented by a single floor and optionally a basement wall. Any ground-adjacent walls linked to the Kiva Foundation are mapped to a single representative wall in the two-dimensional context using an area weighted average for any non-uniform boundary conditions among the walls.

Kiva uses these EnergyPlus boundary conditions to calculate the convective heat gains and surface temperatures for the floor and wall surfaces associated with a single [Kiva foundation](#) object:

- weather data,
- solar position, and
- zone temperatures (from previous timestep),
- zone radiation (solar, IR, etc.)

Because Kiva performs multi-dimensional finite difference calculations, the associated surfaces do not use the same [Solution Algorithm](#) (e.g. CTF, Finite difference etc) as the rest of the model.

Example profile output from standalone Kiva

Example plan output from standalone Kiva

Two-Dimensional Approximation

The two-dimensional approximation method employed by Kiva relies on knowing the footprint shape, area, and exposed perimeter of each instance. The appropriate footprint shape, area, and exposed perimeter for each instance will be defined within the context of the overall geometry of the Foundation surfaces.

The general method is to define the width of the floor (the distance from the symmetry plane to the wall interior), w in the two-dimensional context as:

$$A/P_{\text{exp}}$$

where:

A is the area of the foundation footprint, and,

P_{exp} is the exposed perimeter of the foundation, that is the perimeter of the foundation footprint that is in contact with the ground, as opposed to being in contact with an internal space, see image below.

Note: One of the key inputs for each EnergyPlus Kiva Foundation is the “Exposed foundation perimeter”, i.e. the length of the foundation perimeter edge that is adjacent to the ground. DesignBuilder calculates this behind the scenes based on the model geometry. This is one of the advantages of using DesignBuilder for your Kiva simulations.

Kiva also has the capability to adjust this width to account for concave foundation footprint shapes. This adjustment is based on the boundary layer adjustment method described by Kruis and Krarti (2017). The approach adjusts the exposed perimeter to account for interactions in heat flow within concave corners and narrow gaps between two exposed edges.

This approach allows for accurate representation of building foundation heat transfer without performing three-dimensional calculations. Because the two-dimensional context is symmetric, the domain can be divided in half to further reduce the number of calculations.

Numerical Calculations

Kiva automatically discretises the two-dimensional domain into rectangular cells. The size of each cell is defined by the [Kiva foundation settings](#) object's **Minimum cell dimension** and **Maximum Cell Growth Coefficient**. The **Minimum cell dimension** defines the smallest possible dimension of a cell within the domain. Cells along a block boundary start at this size and grow geometrically away from the boundary according to the “**Maximum cell growth coefficient**”. This is evident from the diagrams below which show the discretisation for a single foundation at close and far perspectives, respectively.

Example generated discretisation near foundation perimeter

Example generated discretisation of full domain

The discretised partial differential equations are solved using the Alternating Direction Implicit (ADI) finite difference time stepping scheme. This scheme provides relatively fast calculations with stable results as demonstrated by Kruis and Krarti (2015).

Boundary Conditions

Boundary conditions in Kiva's two-dimensional context

Symmetry Plane: Zero heat flux in the horizontal direction.

Wall Top: Zero heat flux in the vertical direction (assumes heat transfer through the exterior wall above is one-dimensional in the horizontal direction).

Deep Ground: Either constant temperature or zero vertical heat flux, depending on user input. Deep ground depth may be automatically calculated based on water table estimates using a method defined by Williams and Williamson (1989).

Far-Field: Zero heat flux in the horizontal direction. If this boundary is sufficiently far from the building, this will result in an undisturbed ground temperature profile.

Interior Surfaces:

- Convection is calculated according to the [6-TARP](#) method.
- Long and short wave radiation is passed from EnergyPlus radiant exchange and interior solar distribution algorithms. Note: Kiva uses area weighted averages to define the radiation incident on walls in the two-dimensional context.

Exterior Surfaces:

- Convection is calculated according to the [6-DOE-2](#) method. Wind speeds along the exterior grade are calculated at the roughness height.
- Exterior long wave radiation is calculated using the same algorithms used for other EnergyPlus surfaces. Note: there is no explicit radiant exchange between the ground and building surfaces.
- Exterior solar incidence is uniform along the exterior grade surfaces. No shading is taken into account. Solar incidence along the wall exterior

Multiple Kiva Instances

In some cases, a single Foundation boundary condition might require multiple Kiva instances.

Multiple Zones: If the surfaces in several zones reference the same [Kiva foundation](#) object, each zone will internally be calculated using separate Kiva instances, one per EnergyPlus floor surface.

Walk-Out Basements: Walkout basements are defined by using walls of different heights all referencing the same [Kiva foundation](#) object.

Walkout basement surfaces (in grey) all reference the same Foundation:Kiva object

A separate Kiva instance will be run internally for any walls with different average heights associated with the same [Kiva foundation](#) object.

For non-rectangular surfaces, EnergyPlus uses the average height of each basement wall surface. A separate Kiva instance is created for each wall (or group of walls) with the same average height.

The diagram below shows the grouping of walls by height based on the basement illustrated above, including the portion that is only a slab.

Walkout basement Kiva instances (one for each wall height)

The resulting five two-dimensional contexts will look like the figures below.

Each Kiva instance with a different wall height will calculate different heat fluxes, convective coefficients and surface temperatures for both the wall and the floor. The heat flux through the associated floor will be weighted according to the fraction of the total exposed perimeter, $P_{exp,tot}$, represented by each segment of different height. The total heat flux through the walkout basement floor is:

$$\dot{q} = \sum_i^{N_{segs}} \frac{P_{exp,i}}{P_{exp,tot}} \cdot h_i (T_{\infty} - T_{floor,i})$$

The weighted average convective coefficient for the walkout basement floor surface is:

$$\bar{h} = \sum_i^{N_{wall,segs}} \frac{P_{exp,i}}{P_{exp,tot}} \cdot h_i$$

The weighted average temperature for the floor surface is:

$$\bar{T}_{floor} = T_{\infty} - \dot{q} / \bar{h}$$

Multiple Floor Surfaces: If a floor has multiple constructions (e.g., carpeted and bare) each surface must reference a separate [Kiva foundation](#) object, or be combined into a single equivalent construction.

Core Zone Slabs

Because core zones have no exposed perimeter, they are assumed to exchange heat only with the deep ground boundary condition. This is calculated using a one-dimensional finite difference formulation. The associated Kiva instance will use only the description of the slab and the deep ground boundary condition to define the heat flux through the surface.

Core zone (no exposed perimeter)

Core zone one-dimensional context

Initialisation And Warm-Up

Summary

EnergyPlus uses an accelerated initialisation, which starts with the Kiva [Steady State](#) method. This solution scheme initialises the domain temperatures using the first timestep's boundary conditions in a steady-state finite difference solution, giving an initial condition temperature variation across the domain. EnergyPlus then runs a few months of accelerated (long) timesteps before holding the ground state constant for warm-up days to ensure that the warmup simulations don't erase the thermal history of the ground.

Detail

The traditional “warm-up” (aka preconditioning) period in EnergyPlus (of repeating a single day) presents some challenges for foundation heat transfer calculations:

- As the ground can have time constants on the order of years, a single day is simply not long enough to adequately capture the thermal history of the ground.
- Any repetition of a single day would erase any pre-calculated thermal history and likely take much longer to converge.

Instead, Kiva instances are initialized independently from the rest of the simulation using the accelerated initialisation method developed by Kruis (2015). This method analyses the weather file and simulates long timestep (in the order of weeks or months) calculations using an implicit numerical scheme. These long timesteps allow Kiva to capture a long term history of the ground without running the entire building model.

The initialisation of the ground domain can either use a [user-defined value](#) for the temperature of adjacent buildings, or the indoor air temperatures can be inferred (as they are not yet calculated by EnergyPlus). In the latter case, when a thermostat is assigned to a zone with Kiva foundation surfaces, the setpoint (or a weighted average of heating and cooling setpoints depending on the outdoor temperature) is used. Alternatively, for zones without thermostats, a constant 22°C indoor temperature is assumed.

HVAC Autosizing

In EnergyPlus HVAC autosizing calculations, the state of the Kiva ground domain is approximated by running a few long timestep simulations (in the order of months) using some basic assumptions about the state of the building. EnergyPlus holds the ground constant in this initial state during warmup but allows it to vary during the autosizing calculations themselves. This process helps to ensure reasonable convergence times.

Kiva Limitations

Some limitations in the current implementation of Kiva are:

1. Only floors and walls can connect to the ground through Kiva foundation boundary conditions.
2. At least one floor surface must reference each Kiva foundation object.
3. To model 2 stories at -1 and -2 levels using Kiva requires a workaround since when using Kiva for a zone in EnergyPlus, that zone must have one floor surface touching ground for Kiva to calculate heat transfer. There are 2 ways to do this:
 - a. Keep the zones stacked, but use Kiva for only the -2 level zone and change the boundary condition for the walls of the -1 level zone to use standard ground modelling, i.e. uncheck the [Kiva adjacency](#) checkbox for these wall surfaces. This is necessary because a Kiva wall from upper zone can't be connected to the floor of the zone below and Kiva walls must be connected to a Kiva floor.
 - b. [Merge the two zones](#) together to remove the ceiling for the -2 level zone and floor for the -1 level zone and modelling that surface as "Internal Thermal Mass" on page 363 instead.The second option would generally be the easiest and most accurate choice.
4. Kiva ground modelling is not compatible with Fanger PMV temperature control in E+ v9.4. The bug is fixed in E+ v9.6 and later.
5. Outputs for surfaces with a Foundation boundary condition type will include all opaque surface output variables except:
 - o Surface Outside Face variables (since there is no “Outside Face”).
 - o Surface Heat Storage variables (since this definition depends on an “Outside Face”).
 - o Surface Internal Source Location Temperature (Kiva doesn't handle internal sources yet, but this is a possible future enhancement).
6. Kiva is not compatible with F-Factor constructions used in Kiva ground adjacent surfaces. This means that you should not use Kiva for LEED and ASHRAE 90.1 Appendix G simulations.
7. Kiva is not compatible with constructions with [Simple resistance](#) (R-value) material layers in Kiva ground adjacent surfaces.
8. Kiva is not compatible with constructions with an internal source (e.g. underfloor heating) used in Kiva ground adjacent surfaces. You can use surfaces with an internal source in any other surface in Kiva simulations though. See [EnergyPlus issue #6576](#).

9. The Kiva ground domain is not used by Detailed HVAC [Ground heat exchangers](#) which have their own representation of the ground temperature field, typically based on G-function data for [vertical ground heat exchangers](#).

Validation

Kiva has been tested against the BESTEST Ground coupled cases with accuracy within 3% of the reference solutions (Kruis and Krarti, 2015).

Horizon

[Location tab](#) on model data at Site level

You can add a horizon to your model to include the effects of terrain or more distant tall buildings on the shading of the simulated building. Horizons are modelled by defining a horizon elevation angle for each direction (azimuth) around the building.

The horizon data is used in Cooling design calculations and EnergyPlus Simulations, but not in Daylighting simulations and Visualisations.

Note: To include the shading effect of *nearby* buildings you should generally use component blocks to represent those buildings for most accurate modelling. This is more accurate because their proximity to the modelled building will give rise to different horizon elevations for different parts of the building. The horizon system on the other hand would not capture this as it generates distant shading objects (100m away from the building by default) which for most buildings will provide an approximately constant horizon for all parts of the building.

Include horizon in the model

Check this option to include the effects of terrain such as mountains, hills or more distant buildings.

Horizon component

Select the [horizon component](#) that defines the elevation of the horizon for each azimuth angle around the building.

Site Details - Mains Water Temperature

[Location tab](#) on model data at Site level

The Water Mains Temperature data is used to calculate water temperatures delivered by underground water main pipes. The mains temperatures are used as default, make-up water temperature inputs for the [Water](#)

[heater](#). The mains temperatures are also used in the water systems objects to model the temperature of cold water supplies.

Note: This data is only used when using Detailed HVAC. For Simple HVAC a single annual average mains water temperature is defined under the [DHW](#) header on the HVAC tab.

Water mains temperatures are a function of outdoor climate conditions and vary with time of year. A correlation has been formulated to predict water mains temperatures based on two weather inputs:

- Average annual outdoor dry-bulb air temperature.
- Maximum difference in monthly average outdoor air temperatures.

These values can be easily calculated from annual weather data using a spreadsheet or from the ".stat" file available with the EnergyPlus weather files at www.energyplus.gov. Monthly statistics for dry-bulb temperatures are shown with daily averages. The daily averages are averaged to obtain the annual average. The maximum and minimum daily average are subtracted to obtain the maximum difference. For more information on the water mains temperatures correlation, see the EnergyPlus Engineering Document.

Alternatively, the water mains temperatures can come from a schedule. This is useful for measured data or when water comes from a source other than buried pipes, e.g., a river or lake.

Calculation method

Select from the options:

- **1-Schedule** where the water mains temperature is scheduled.
- **2-Correlation** where the water mains temperature is calculated from the average outdoor air temperature and range of monthly outdoor air temperatures.

Schedule

If the Calculation method is **1-Schedule**, the water mains temperatures are read from the schedule referenced by this field. Note that the schedule temperatures must be in °C even when using IP units.

Annual average outdoor air temperature

If the Calculation method is **2-Correlation**, this field is used in the calculation as the annual average outdoor dry-bulb air temperature (in °C or °F).

Maximum difference In monthly average outdoor air temperatures

If the calculation method is **2-Correlation**, this field is used in the calculation as the maximum difference in monthly average outdoor air temperatures (in Δ°K or Δ°F).

Site Details - Precipitation + Irrigation

[Location tab](#) on model data at **Site level**

Precipitation

[Location tab](#) on model data at **Site level**

The Site precipitation data is used to describe the amount of precipitation on all **Green roof** surfaces over the course of the simulation. Precipitation includes both rain and the equivalent water content of snow. Precipitation is not yet described well enough in the usual building weather data file. So this object is used to provide the data using Schedule objects that define rates of precipitation in meters per hour. A set of schedules for site precipitation have been developed for USA weather locations and are provided with EnergyPlus in the data set called "PrecipitationSchedulesUSA.idf." The user can develop schedules however

they want. The schedules in the data set were developed using EnergyPlus' weather file (EPW) observations and the average monthly precipitation for the closest weather site provided by NOAA. EPW files for the USA that were based on TMY or TMY2 include weather observations for Light/Moderate/Heavy rainfall, however most international locations do not include these observations. The values were modeled by taking the middle of the ranges quoted in the EPW data dictionary. The assumed piecewise function is shown below.

Amount m/h	Light 0.0125	Medium 0.052	Heavy 0.1
---------------	-----------------	-----------------	--------------

The values were inserted on hour by hour basis for the month based on the observations. Then each month was rescaled to meet the average precipitation for the month based on the 30-year average (1971-2000) provided by the NOAA/NCDC. Therefore, the flags in the EPW file match the precipitation schedules for the USA. Note that summing the average monthly precipitation values will not give you the average yearly precipitation. The resulting value may be lower or higher than the average yearly value. Once the typical rainfall pattern and rates are scheduled, the Site Precipitation data provides a method of shifting the total rainfall up or down for design purposes. Wetter or drier conditions can be modelled by changing the Design Annual Precipitation although the timing of precipitation throughout the year will not be changed.

Design annual precipitation

Magnitude of total precipitation for an annual period to be used in the model. Value selected by the user to correspond with the amount of precipitation expected or being assumed for design purposes. The units are in meters. This field works with the following two fields to allow easily shifting the amounts without having to generate new schedules. Units are m/yr or ft/yr

Precipitation schedule

The schedule that describes the rate of precipitation. The precipitation rate schedule is analogous to weather file data. However, weather files for building simulation do not currently contain adequate data for such calculations. Therefore, EnergyPlus schedules are used to enter the pattern of precipitation events. The values in this schedule are the average rate of precipitation in meters per hour. The integration of these values over an annual schedule should equal the nominal annual precipitation.

Nominal annual precipitation

Magnitude of annual precipitation associated with the rate schedule. This value is used to normalize the precipitation.

Site Green Roof Irrigation

The Site Roof irrigation data is used to describe the amount of irrigation on all **Green roof** surfaces over the course of the simulation. You can define time-varying irrigation data using a maximum irrigation value and a schedule. There is also an option to apply some intelligence to the irrigation system to avoid over-watering the green roof.

Irrigation type

Defines the way irrigation water is supplied. Select from:

- **1-Scheduled** - water is proved using the maximum irrigation rate and schedule modifier (below).
- **2-Smart** - as Scheduled but overrides the irrigation to be off when the earth is 30% or more saturated with water.

Max irrigation rate

Maximum rate of irrigation per hour. Units are m/h or ft/h.

Irrigation schedule

The schedule defining the operation of the irrigation system. A schedule value of zero means the irrigation is switched off and a value of 1 means that the **Max irrigation rate** is used.

Site Details - Outdoor Air CO2 And Contaminants

[Location tab](#) on model data at [Site level](#)

The Outdoor air CO2 and generic contaminants data at site level provides a way to select which contaminant types will be simulated. Although carbon dioxide is not normally considered to be an indoor contaminant it is used as an indicator of indoor air quality in buildings. From the simulation point of view EnergyPlus treats carbon dioxide as a type of contaminant. In addition to carbon dioxide, a generic contaminant type model is available.

These options should be selected if you wish to model CO2 or contaminant concentration levels in the simulation, either to monitor zone air quality or if [DCV control](#) is being used.

Note: DesignBuilder automatically selects the **CO2 concentration** and **Generic contaminant concentration** options below as appropriate if you have one of the IAQP DCV systems requiring CO2 or generic contaminant tracking selected in a Detailed HVAC model.

Simulate CO2 concentration

Check this option if simulation of CO2 concentration levels are to be performed.

CO2 concentration schedule

Select the schedule that defines outdoor air carbon dioxide level values in units of ppm. The default schedule defines outdoor constant CO2 concentration at 400ppm based on NOAA ESRL sources.

Simulate contaminant concentration

Check this option if simulation of contaminant concentration levels are to be performed.

You can enter details on zone [contaminant generation and removal](#) on the Activity tab.

Contaminant schedule

Select the schedule that defines outdoor air contaminant level values in units of ppm.

Time And Daylight Saving

[Location tab](#) on model data at [Site level](#)

Time zone

Select the [Time zone](#) for the site location. The time zone defines both the standard time meridian and information on daylight saving. Generally you should leave this as the default for the location.

You can override daylight savings to be off by unchecking the **Use daylight saving** model data.

DesignBuilder models the effect of daylight saving time where the clocks are moved forward one hour in the summer months in most non-equatorial countries. The timing of this is handled automatically using the [Time zones database](#) when you load data from one of the [Location templates](#) supplied with the program.

There are some factors you should be aware of:

- In EnergyPlus, summer Daylight saving works by adding the number of hours specified in the Time zone data (usually 1 hour) to the local mean time to get the time to determine schedule operation. Because [Simulation results](#) are displayed in **local mean time**, during the summer when daylight saving time is in use, occupancy and equipment etc will appear to start 1 hour earlier in the day than it does in

the winter. To help you pinpoint this, DesignBuilder prints the times when daylight saving starts and ends on the graph.

- When comparing results with and without Daylight saving you will notice:
 - Solar radiation data has exactly the same timing with and without daylight saving.
 - Occupancy, equipment (and other aspects of building operation controlled by schedules) will start 1 hour earlier with daylight saving.
- [Visualisations](#) use local mean time when setting the position of the sun for site shading analysis. Again you can account for daylight saving time by adding 1 hour to the time during summer months to see shading for local clock time.

See also:

- [Hourly and Sub-Hourly Results Times](#)

Start/End of Winter/Summer

These settings are loaded from the [Location template](#) and cannot be edited in Model data.

For Northern hemisphere locations you should normally expect to see data like:

- Start of Winter = Oct
- End of Winter = Mar
- Start of Summer = Apr
- End of Summer = Sep

For Southern hemisphere locations you should normally expect to see data like:

- Start of Winter = Apr
- End of Winter = Sep
- Start of Summer = Oct
- End of Summer = Mar

Note: It is important that the selected months cover the entire year.

Simulation Weather Data

[Location tab](#) on model data at [Site level](#)

Hourly weather data

Select the hourly weather data from the list of Hourly weather data components. These components reference the epw file that will be actually used in the simulation.

DesignBuilder uses EnergyPlus epw format hourly weather data for:

- [EnergyPlus simulations](#) - note that heating and cooling design calculations use simpler design weather data.
- [Daylighting annual simulations](#) - in this case the weather data is used to provide Radiance with hourly direct and diffuse illuminance data for the site.

There is no direct link between hourly weather data and the ASHRAE design values on the [Winter](#) and [Summer](#) design data tabs.

You can review, edit and convert weather using the [Weather Data Analysis dialog](#).

You can also [add your own hourly weather data](#).

See also the [Site level data and weather files](#) and [Hourly weather data](#) tutorials.

Day of week for start day

For flexibility, the day of week indicated in the weather file can be overridden by this field's value. Select from:

- **1-Sunday**,
- **2-Monday**,
- **3-Tuesday**,
- **4-Wednesday**,
- **5-Thursday**,
- **6-Friday**,
- **7-Saturday**,
- **8-Use weather file** - use the weather file to decide the first day of the week.

This value will be used as the Start day of the week for the simulation. The default is **8-Use weather file** where the day of week comes from the weather file.

Note: There is an option to [specify](#) the [Start year](#) of the simulation on the Simulation Calculation options dialog. When the start year is specified it overrides this setting and the year will define the day of the week of the start day.

Winter Design Weather Data

[Location tab](#) on model data at [Site level](#)

Heating design and simulation autosizing simulations use simplified winter design weather based on a worst case design day.

The weather data used in [Heating design calculations](#) is as follows:

- **Minimum outside dry-bulb temperature** - the winter design outside air temperature.
- Co-incident **Wind speed**. This data is used to help calculate external convective heat transfer coefficients.

In addition for zone heating load autosizing this additional data is used:

- Coincident **Wind direction** is used in Calculated natural ventilation autosizing calculations (along with the wind speed above).

The degree of 'confidence' of the design data can be selected, i.e. the probability that the design data will occur in practice based on conditions encountered over recent years. Select either 99.6 or 99% confidence (i.e. 0.4 or 1% chance of more extreme winter weather occurring).

See also the [Site level data and weather files](#) and [Heating Design Calculations](#) tutorials

Sizing Period

When running simulations, some design features may benefit by using a longer design weather period for HVAC autosizing or loads calculations. Longer design periods may be set up by allowing the hourly weather file to be used in the sizing calculations.

Autosize method

Choose the design HVAC autosizing method to use for simulations from the following options:

- **1-Design day**, the default option where data for a single winter design day is used based on the settings described above.
- **2-Weather file days** where you can select the period to be used from the weather file for sizing.
- **3-Weather file condition type** where you can select from some standard per-defined types of period such as **3-Winter extreme**.

When **2-Weather file days** is selected, enter the From **Start day** and **Month** and the To **Start day** and **Month** as shown in the screenshot below.

Sizing Period	
Autosize method	2-Weather file days
From	
Start day (°)	1
Start month	Dec
To	
End day (°)	7
End month	Dec

Period selection

When the **3-Weather file condition type** Autosize method is selected you must choose the Weather file condition type from the following list.

- **1-Summer extreme**
- **2-Summer typical**
- **3-Winter extreme** (default setting)
- **4-Winter typical**
- **5-Autumn typical**
- **6-Spring typical**
- **7-Wet season**
- **8-Dry season**
- **9-No wet season**
- **10-No dry season**
- **11-Tropical hot**
- **12-Tropical cold**

Note: Not all weather files have all of the valid choices so this option is not completely generic. For example there may be extreme cold periods in some weather files but extreme wet periods (tropical) in others.

Summer Design Weather Data

[Location tab](#) on model data at [Site level](#)

Cooling design and simulation autosizing simulations use simplified summer design weather based on worst-case design days.

The weather data used in [cooling design calculations](#) is as follows:

- Maximum outside dry-bulb temperature - the maximum dry bulb air temperature over the day
- Minimum outside dry-bulb temperature - the minimum dry bulb air temperature (night time)

- Wet-bulb temperature at the time of the maximum dry-bulb temperature.

In addition for zone cooling load simulation autosizing this additional data is used:

- Dry bulb temperature range modifier type to help define the daily profile of the outside air temperature
- Wind speed and direction for use in Calculated natural ventilation autosizing calculations.

The degree of 'confidence' of the design data can be selected, i.e. the probability that the design data will occur in practice based on conditions encountered over recent years. This risk can be specified based on dry or wet-bulb temperatures, for 99.6, 99 and 98% confidence (i.e. 0.4, 1 or 2% chance of more extreme weather occurring).

See also the [Site level data and weather files](#) and [Cooling Design Calculations](#) tutorials

Sky

Solar model indicator

Choose the method to be used for solar modelling in the calculation of the solar radiation in the summer design day(s):

- **1-ASHRAE Clear Sky**, the default model described in ASHRAE HOF 2005 Chapter 31, can be used to estimate hourly clear-day solar radiation for any month of the year in U.S. or similar temperate climates in the northern hemisphere. EnergyPlus calculations extend the clear sky application to both northern and southern hemispheres. Calculations use a [Clearness](#) value as part of their calculations. The Clear Sky model usually over estimates the amount of solar radiation available to the building.
- **2-ASHRAE Tau**, aka the ASHRAE Revised Clear Sky Model is introduced in the ASHRAE 2009 HOF as a revised clear sky model based on location-specific optical depths for direct and diffuse radiation. These values are tabulated by month for all 5564 locations in the ASHRAE design data that accompanies the 2009 HOF. This data is included with EnergyPlus installations in C:\EnergyPlusV8-9-0\PreProcess\WeatherConverter\ASHRAE_2013_Monthly_DesignConditions.csv. The Taub and Taud design values for each month of the year are provided in the first 24 data columns. Studies done as part of ASHRAE research projects show that the revised tau model produces more physically plausible irradiance values than does the traditional clear sky model. In particular, diffuse irradiance values are more realistic. Taub and Taud values can be entered as described below.
- **3-Zhang Huang**, developed for initial use in modelling typical meteorological years for China weather sites, this model seems to be good for other locations as well. Using total cloud cover, dry-bulb temperature, relative humidity, and wind speed as the independent variables, the total (global horizontal) solar radiation is estimated through a simple equation. This is the same model used to estimate the global solar radiation value when it is absent from the source data in the Weather Converter. Calculations use a [Clearness](#) value as part of their calculations.
- **4-Schedule**, allows you to enter custom Beam solar day and Diffuse solar day scheduled values for the day's profile (below).

Beam solar day schedule

Select your own custom day profile of beam solar values (Wh/m²) when the [Solar model indicator](#) is selected as **4-Schedule**. These values will replace the calculated values during design day processing. Only [Day schedules](#) can be selected here.

Diffuse solar day schedule

Select your own custom day profile of diffuse solar values (Wh/m²) when the [Solar model indicator](#) is selected as **4-Schedule**. These values will replace the calculated values during design day processing. Only [Day schedules](#) can be selected here.

ASHRAE clear sky optical depth for beam irradiance (Taub)

The Optical depth for beam radiation must be entered when the [Solar model indicator](#) is selected as **2-ASHRAE Tau**. Taub and Taud values are tabulated by month for 5564 locations worldwide on the CD that accompanies the ASHRAE 2009 HOF and in ASHRAE_2013_Monthly_DesignConditions.csv that is installed with EnergyPlus.

ASHRAE clear sky optical depth for diffuse irradiance (Taud)

The Optical depth for diffuse radiation must be entered when the [Solar model indicator](#) is selected as **2-ASHRAE Tau**. Taub and Taud values are tabulated by month for 5564 locations worldwide on the CD that accompanies the ASHRAE 2009 HOF and in ASHRAE_2013_Monthly_DesignConditions.csv that is installed with EnergyPlus.

Sky clearness

The sky “clearness” index for the summer design day and must be entered when the [Solar model indicator](#) is selected as **1-ASHRAE clear sky** or **3-Zhang Huang**. Along with the solar position as defined by the Location information and the date, this value helps define the solar radiation for each hour of the design day. Clearness may range from 0.0 to 1.2, where 1.0 represents a clear sky at sea level. Values greater than 1.0 may be used for high altitude locations.

Note: This “sky clearness” does not have the same meaning as the EnergyPlus output variable “Site Daylighting Model Sky Clearness”.

Weather Data Modifiers

The daily temperature profile used in the cooling design calculations is calculated from the maximum and minimum values using a modified sinusoidal curve and assuming that the maximum temperature occurs at 15:00 and the minimum at 5:00. You can change this behaviour by using the data described below.

Dry-bulb temperature range modifier type

DesignBuilder provides some options to give more control over the dry-bulb temperatures used for the design days:

- **1-Default multipliers** - where EnergyPlus automatically generates the outside dry-bulb temperature profile based on the data provided in ASHRAE 2009 HOF.
- **2-Multiplier schedule** - where you can define a day schedule that specifies a multiplier applied to the daily temperature range to create the proper dry-bulb temperature range profile for your design day. This works as described below.
- **3-Temperature profiles** - allows you to use a Dry-bulb temperature profile schedule to define the dry-bulb temperature for the design day.

Important note: When using multiple summer design months these options are applied identically for each month. They are therefore generally of more use for single design months, i.e. when **1-Single design month** is selected as the [Design temperature period](#).

When using the **1-Default multipliers** option, the multipliers are taken from the ASHRAE 2009 HOF. More specifically, EnergyPlus creates an air temperature for each timestep by using the entered maximum dry-bulb temperature in conjunction with the entered daily range and the above multiplier values. The actual equation used is shown below:

$$T_{\text{current}} = T_{\text{max}} - T_{\text{range}} \times T_{\text{multiplier}}$$

where:

T_{current} = Air temperature of current hour of day

T_{Max} = User supplied Max Dry-bulb Temperature

T_{range} = The daily temperature range ($T_{\text{max}} - T_{\text{min}}$)

$T_{\text{Multiplier}}$ = Range multiplier as shown on the above graph

The range multiplier values represent typical conditions of diurnal temperatures (i.e. the low temperature for the day occurring about 5:00 AM and the maximum temperature for the day occurring about 15:00. Note that EnergyPlus does not shift the profile based on the time of solar noon as is optionally allowed in ASHRAE procedures.

ASHRAE research indicates that dry-bulb and wet-bulb temperatures typically follow the same profile, so EnergyPlus can use the default profile to generate humidity conditions.

Dry-bulb temperature range modifier schedule

If you would like to override the default ASHRAE profile you can select the **2-Multiplier schedule** option for the [Dry-bulb temperature range modifier type](#) setting. This shows allows a Day schedule to be selected to define the range multipliers for each time of the cooling design day.

Dry-bulb temperature profile schedule

Select the Day schedule to be used to represent the dry-bulb temperature for the design day.

Note: The temperature values in the schedule must be defined in °C even when SI units are selected.

Humidity condition type

This option allows the method to be used to define humidity to be defined. It is only made available when the Dry-bulb temperature range modifier type is set to **3-Temperature profiles**. Select from:

- **1-Wet-bulb**, the default option where a wet-bulb temperature at the time of maximum temperature is used. The as defined using the coincident wet-bulb temperature further down the data sheet.
- **2-Relative humidity**, where the hourly variation of relative humidity is defined using the [Humidity condition schedule](#).

Humidity condition schedule

Select the Day schedule which defines the relative humidity in %.

Wind Data

Wind speed

This is the wind speed to be used for calculating the exterior convective heat transfer coefficients and for use (only in Calculated natural ventilation autosizing simulations) for calculating the exterior wind pressure along with the surface [wind press coefficients](#).

Wind direction

Used only for only in autosizing simulations of Calculated natural ventilation models for calculating the exterior wind pressure along with the surface [wind press coefficients](#).

Sizing Period

When running simulations, some design features may benefit by using a longer design weather period for HVAC autosizing or loads calculations. Longer design periods may be set up by allowing the hourly weather file to be used in the sizing calculations.

Autosize method

Choose the design HVAC autosizing method to use for simulations from the following options:

- **1-Design day** - the default option where data for one or more summer design days is used based on the settings described above.
- **2-Weather file days** where you can select the period to be used from the weather file for sizing.
- **3-Weather file condition type** where you can select from some standard per-defined types of period such as **1-Summer extreme**.

When **2-Weather file days** is selected, enter the From **Start day** and **Month** and the To **Start day** and **Month** as shown in the screenshot below.

Sizing Period	
Autosize method	2-Weather file days
From	
Start day (°)	17
Start month	Aug
To	
End day (°)	23
End month	Aug

Period selection

When the **3-Weather file condition type** Autosize method is selected you must choose the Weather file condition type from the following list.

- **1-Summer extreme** (default setting)
- **2-Summer typical**
- **3-Winter extreme**
- **4-Winter typical**
- **5-Autumn typical**
- **6-Spring typical**
- **7-Wet season**
- **8-Dry season**
- **9-No wet season**
- **10-No dry season**
- **11-Tropical hot**
- **12-Tropical cold**

Note: Not all weather files have all of the valid choices so this option is not completely generic. For example there may be extreme cold periods in some weather files but extreme wet periods (tropical) in others.

Design Temperature Period

The design month for cooling design and autosizing simulations is not always clear from the outset and indeed is often different for different parts of the same building. You can therefore select up to 12 design months to be used in cooling design and autosizing simulations.

You can choose to enter design data for either 1 or multiple months:

- **1-Single design month** where a single set of worst case design data is used for cooling design and autosizing simulations. In this case the design data is typically for the month of July in the Northern hemisphere and January in the Southern hemisphere.
- **2-Multiple design months** where design data for more than one month is used for cooling design and autosizing simulations. In this case the range of months to be used are selected on either the Cooling design calculation options or Model options dialog and the design data to be used for each month is specified here on the Location tab.

Tip: The **2-Multiple design months** option is the safest choice as the peak cooling month may vary across the building depending on the amount of glazing and shading on each façade. For example, for buildings in the Northern Hemisphere, large areas of glazing on south-facing façades may cause the peak design month to be delayed until August or even September when the sun is lower in the sky.

Note: The details of the design day(s): day of the month, the month range and day of week to be used for the Cooling design analysis can be defined on the Model options and [Cooling design](#) dialogs.

ASHRAE Summer Design Data

DesignBuilder includes a wide range of design data suitable for use with both the multiple and single design month options for over 6,400 locations around the world. The data supplied is all based on the ASHRAE 2013 design data set and is licensed from ASHRAE. It is included in the [Location templates](#) database so the appropriate data is loaded to the model when you select the location of your project.

If your precise project location is not included in the ASHRAE database, or if you need to access design data from more recent ASHRAE handbooks, there is a free utility at ashrae-meteo.info/v2.0 which identifies the nearest stations to your project location with distances and provides design data for each station.

Yearly Design Temperatures

When the Design temperature period is selected as **1-Single design month** the following data can be entered for a single month.

Dry-bulb and mean coincident wet-bulb data

- **Max dry-bulb temperature** - the maximum dry bulb air temperature over the day.
- **Coincident wet-bulb temperature** - the wet-bulb temperature at the time of the maximum dry-bulb temperature.
- **Min dry-bulb temperature** - the minimum dry bulb air temperature (night time). The template values have been calculated by DesignBuilder by subtracting the 0.4% Monthly Design Dry Bulb Temperature with the Mean Daily Dry Bulb Temperature Range Coincident with 5% Design Dry Bulb Temperature.

Wet-bulb and mean coincident dry-bulb data

- **Max wet-bulb temperature** - the maximum wet-bulb air temperature over the day.
- **Coincident dry-bulb temperature** - the dry-bulb temperature at the time of the maximum wet-bulb temperature.
- **Min dry-bulb temperature** - the minimum dry-bulb air temperature (night time). The template values have been calculated by DesignBuilder by subtracting the 0.4% Monthly Design Dry Bulb Temperature with the Mean Daily Dry Bulb Temperature Range Coincident with 5% Design Dry Bulb Temperature.

Monthly Design Temperatures

When the Design temperature period is selected as **2-Multiple design months** then the following data can be entered for 12 months.

Dry-bulb and mean coincident wet-bulb data

- **Monthly Design Dry-Bulb Temperatures** - the maximum dry bulb air temperatures over the design day for each month.
- **Monthly Coincident Wet-Bulb Temperatures** - the wet-bulb temperatures at the time of the maximum dry-bulb temperature.
- **Monthly Minimum Dry-Bulb Temperatures** - the minimum dry bulb air temperature (night time).

Wet-bulb and mean coincident dry-bulb data

- **Monthly Design Wet-Bulb Temperatures** - the maximum wet-bulb air temperatures over the design day for each month.
- **Monthly Coincident Dry-Bulb Temperatures** - the dry-bulb temperatures at the time of the maximum wet-bulb temperature.
- **Monthly Minimum Wet-Bulb Temperatures** - the minimum wet-bulb air temperature (night time).

Legislative Region And Insulation Standards

Region tab on model data at [Site level](#)

The data on the tab is related to the [Legislative Region](#) and associated insulation standards of the site.

Legislative region

A Legislative region in DesignBuilder is typically a whole country or a region, province or state within a country which has its own building control powers. The legislative region contains information on:

- Local energy codes and building regulations
- [Fuel emission factors](#) for a range of fuels.

Include Fuel Emissions

You can optionally request fuel emissions output data from EnergyPlus simulations for each fuel individually. Outputs are requested individually because a large number of pollutants are involved for each fuel. When this data is requested the pollution caused by each fuel type is reported in the eso file and a summary is provided in the Summary output file.

Include Fuel Emissions	
☒	Electricity
☒	Natural gas
☐	Fuel oil 1
☐	Fuel oil 2
☐	Coal
☐	Gasoline
☐	Propane
☐	Diesel
☒	Other fuel 1
☐	Other fuel 2

The fuel emission factors used in EnergyPlus' emission calculations comes from [Emissions factor](#) selection on the [Emissions](#) tab of the [Legislative regions template dialog](#). Inputs are only included in EnergyPlus input data for the fuels selected here.

Energy Codes/insulation Standards

[Region tab on model data at Site level](#)

You can select the Mandatory energy code in force as well as three additional levels of reference insulation standards to represent buildings with 'Uninsulated', 'Stock average' and 'Best practice' construction standards.

This data is used:

- To identify the mandatory energy code in force in the region. When one of the ASHRAE 90.1 codes are selected this has a significant knock on impact on the rest of the model as described in the [ASHRAE 90.1 Modelling](#) section.
- To set the insulation levels used when the 'Pre-design' Construction and glazing Model option is selected.
- When calculating asset ratings.
- Defines the [Fuel emissions factors](#) for the region.

Note: If you change any of this data, the insulation standards of the constructions in the <System> category will be automatically updated.

Building Model Data

Building Model Data can be entered at building, block, zone and surface levels (but not at site level). The set of data shown will depend on the level in the hierarchy (building, block etc) and on the Model options selected.

Building Model Data is laid out on the tabs:

- [Activity](#)
- [Construction](#)
- [Openings](#)
- [Lighting](#)
- [HVAC](#)
- [On Site Electricity Generation Data](#)
- [Economics](#)
- [Options](#)
- [CFD](#)
- [Detailed Equipment](#)

Each of these categories of data has a template selection at the top of the tab allowing rapid loading of the data from template.

Model data colour

Default data is [inherited](#) from the level above in the hierarchy and is shown in [blue](#), while 'user data', i.e. data you have explicitly set (or loaded from template) is shown in [red](#). You can clear user data back to its default state so it inherits from the level above using the [Clear data to default](#) command.

See also [Component](#) and [Template list item colours codes](#)

Tip: Use DesignBuilder defaults wisely! Take care to enter the minimum amount of data to get the most from the inheritance system. For example if all zones in a particular block have the same activity called say 'Office work', you should set the activity at block level and not multiple times at zone level. Equally if all the blocks in the building have the same activity, you should set the data at the building level and allow the blocks to inherit the data from the building. By keeping the amount of user data to a minimum, you will find it quicker to make changes at a later date. Clearly it is much faster to change a few Model Data items at building and block level than it is to make multiple changes at zone or surface levels.

See also section on [Model Data Hierarchy & Data Inheritance](#).

Activity Model Data

Activity tab in model data

See also the [Activity data templates and time schedules](#) tutorial

Data on the Activity tab allows you to define the activity (usage) of the zones including information on:

- [Zone Type \(block and zone level only\)](#)
- [Zone Multiplier](#)
- [Include zone](#) [Ref-1310383514](#)
- [Floor Areas and Volumes](#)
- [Occupancy](#)
- "Contaminant Generation and Removal" on page 338
- [Holidays \(building level only\)](#)
- [Environmental control](#)
- [Domestic Hot Water \(DHW\)](#)
- [Computer gains](#)
- [Office equipment gains](#)
- [Miscellaneous gains](#)
- [Catering gains](#)
- [Process gains](#)

You can load generic activity data by clicking on the Template browse control under the Activity Template header and then by clicking on the '...' at the right of the line (below).

When you make a selection from the list of [Activity templates](#), data from selected template will be loaded to the model.

Alternatively you can use the [Load data from template](#) tool.

Note that the appropriate [Sector](#) is loaded with the activity (screenshot above). The Sector is for information purposes only and does not affect the simulations.

All Activity data (apart from Holidays) is used to generate simulation data at the **Zone level**. Holiday data is used at **Building level**.

See also the [Activity data templates and time schedules](#) tutorial

Zone Type

[Activity tab](#) in model data under Activity Template header

The zone type can be set at block or zone level on the Activity tab. The options depend on whether you are working on an ASHRAE 90.1 model or not. **If it is not an ASHRAE 90.1 model** then the Zone type can be one of:

- **1-Standard** - the zone is within the main envelope and is usually (but not necessarily) occupied and heated and/or cooled. This zone type also covers zones within the main building envelope that are unoccupied and not directly heated or cooled such as offices that are temporarily unoccupied may come into this category.
- **2-Semi-exterior unconditioned** - the zone is unoccupied and is neither heated nor cooled and lies outside the main building envelope. Examples of unconditioned spaces are roofspaces, sunspaces, crawlspaces, car parks etc.
- **3-Cavity** - the zone is a narrow sealed vertical cavity such as the glazed cavity within a double façade or a Trombe wall. This algorithm calculates the convection coefficients for such a cavity based on the ISO 15099 standard.
- **4-Plenum** - the zone is a plenum which is unoccupied and has no heating, cooling, or mechanical ventilation (though of course air can flow through it to meet the needs of the zones it serves).

Otherwise if it is an **ASHRAE 90.1 model** then the following options are available.

- **1-Conditioned** - the zone is within the main envelope and is usually (but not necessarily) occupied and heated and/or cooled. This zone type also covers zones within the main building envelope that are unoccupied and not directly heated or cooled such as offices that are temporarily unoccupied may come into this category.
- **2-Unconditioned** - the zone is unoccupied and is neither heated nor cooled and lies outside the main building envelope. Examples of unconditioned spaces are roofspaces, sunspaces, crawlspaces, car parks etc. Note: that setting a zone to have 2-Unconditioned zone type does not *ensure* that it has no heating and cooling. You must ensure that through the HVAC system definition.
- **3-Cavity** - the zone is a narrow sealed vertical cavity such as the glazed cavity within a double façade or a Trombe wall. This algorithm calculates the convection coefficients for such a cavity based on the ISO 15099 standard.
- **4-Plenum** - the zone is a plenum which is unoccupied and has no heating, cooling, or mechanical ventilation (though of course air can flow through it to meet the needs of the zones it serves).
- **5-Semiheated** - the zone is heated to a low level only. **This option is only available for ASHRAE 90.1 models.** In exceptional cases where an ASHRAE 90.1 model has been converted to non-ASHRAE 90.1 model, any zones with the **5-Semiheated** zone type are treated as if **1-Standard** had been selected.

Zone types are also described in the [Partitioning blocks to create zones](#) tutorial

Note: Zones having one of the **2-Semi-exterior unconditioned**, **3-Cavity** and **4-Plenum** zone types do not have their floor area included in the building total floor area in the summary reports.

2-Semi-exterior unconditioned

When the Zone type is set to **2-Semi-exterior unconditioned**, the program asks you 'Do you want to load default unconditioned data including Activity, Lighting and HVAC templates?' If you reply 'Yes' then the zone is set as unoccupied by loading **<None>** Activity, HVAC and Lighting template data.

Also [Semi-exposed constructions](#) will be used instead of standard partitions for adjacencies with 'Unconditioned' zones. For example the wall between an occupied office and a car park would use the Semi-exposed construction, whereas the wall between two occupied offices would use Internal partition construction.

2-Unconditioned

When the Zone type is set to **2-Unconditioned**

3-Cavity

When the Zone type is set to **3-Cavity**, the program asks you 'Do you want to load default 'cavity' data including appropriate convection coefficients, calculation options and Activity, HVAC and Construction templates'. If you reply 'Yes' then the following changes are made:

- The zone is set as unoccupied by loading **<None>** Activity, HVAC and Lighting template data.
- Suspended floors and ceilings are switched off.
- The **5-Cavity** [Inside convection algorithm](#) is set for Cooling design, Heating design and simulation calculations.
- The **3-Full interior and exterior** [Solar distribution algorithm](#) is set for Cooling design and simulation calculations.

You can find out more about [Trombe wall simulations](#) in the [Modelling Issues](#) section.

4-Plenum

When the Zone type is set to **4-Plenum**, the program asks you 'Do you want to load default plenum data including appropriate convection coefficients, calculation options and Activity and HVAC templates?'. If you reply 'Yes' then the following changes are made:

- The zone is set as unoccupied by loading **<None>** Activity, HVAC and Lighting template data.
- Suspended floors and ceilings are switched off.
- The **4-Ceiling diffuser** [Inside convection algorithm](#) is set for Cooling design, Heating design and simulation calculations.

You can find out more about modelling plenums under HVAC.

Unconditioned zone type (ASHRAE 90.1 only)

In ASHRAE 90.1 models, when the **2-Unconditioned** Zone type is selected you must define whether the unconditioned zone has normal levels of airtightness, or it is outside the main envelope. The options are:

- **1-General** for unconditioned zones having normal levels of airtightness.
- **2-Ventilated crawlspace/attic etc** for zones outside the main envelope such as attics, crawlspaces and car parking which are unsealed and have no provision for airtightness.

Note: Zones having one of the **2-Unconditioned** zone types and **2-Ventilated crawlspace/attic etc** Unconditioned zone ventilation do not have their floor area included in the building total floor area in the summary reports.

Zone Multiplier

[Activity tab](#) in model data under **Activity Template** header

The Zone multiplier data allows you to reduce the size of your model in cases where there are similar zones by specifying that certain zones are repeated and so only need to be simulated once. A typical use is for multi-storey buildings with identical (or very similar) floors, for example, a hotel where there is a standard room layout on each floor that is repeated many times. The image below is taken from the **Zone Multiplier Example.dsb** file provided with the software and illustrates how the zone multiplier mechanism works.

The basic 7 storey building on the left above doesn't use the zone multiplier and, since each storey has one zone, the whole building contains 7 zones. The equivalent building on the right has been simplified by using the zone multiplier. The single mid-storey zone has a zone multiplier of 5 which means that during the simulation the zone is treated as if there were 5 of them. In particular the energy consumption and HVAC airflow rates are multiplied by 5 so the results for the reduced building match approximately with that of the non-reduced model.

The top floor and ground floor zones cannot be combined using the zone multiplier because they have roof and ground adjacencies respectively and so must be retained in the reduced model. However the 5 mid-floor zones all have the same operation and adjacencies and so can be combined.

Note: The **Zone multiplier** data is only used at zone level to multiply up zones. The settings at building and block level are there only to allow zone defaults to be set for multiplying zones quickly and easily, they do not multiply blocks or buildings.

See also the [Activity data templates and time schedules](#) tutorial.

Note: The **Zone multiplier** is not currently used in Daylighting calculations and reporting.

Adiabatic Component Blocks

Note the use of the [adiabatic component blocks](#). These have various functions:

- Set the adjacency to be adiabatic for the underside of the top floor zone, the top and underside of the mid-floor zone and the top of the ground floor zone.
- Help to position the mid-floor representative zone in a reasonable representative position to ensure that a good average wind speed will be applied.
- Ensures correct shading in a more complex model. Shadows will be correctly cast by 'missing zones' and also shading received by the representative mid-floor zone will be representative of the shading received by all of the actual mid-floor zones.
- Improves the look of the reduced model to match that of the full model.

For other ways to simplify models see [Simplification](#) on the Advanced tab of the Model options.

Include Zone

[Activity tab](#) in model data under **Activity Template header**

Include zone in thermal calculations

By default all zones are included in simulations and heating and cooling design calculations, but some zones can be excluded through use of this checkbox if necessary. For example, you may wish to exclude a zone or series of zones from the analysis to focus on a smaller part of the building such as a single shop within a shopping mall, and in this case you should uncheck this option on the Activity tab for zones to be excluded as appropriate.

During the simulation:

- Surfaces between included and excluded zones are modelled as being **adiabatic**, i.e. heat is transferred into the wall mass as if the temperature of the excluded zone is the same as that of the included zone.
- Depending on the setting of the [Include shading from excluded zones in simulation](#) model option, surfaces from excluded zones are either represented simply as shading surfaces to ensure that their impact on the solar gains and daylighting in the included zone(s) is still accounted for, or they are ignored altogether.

Note: In Calculated natural ventilation models you should be careful when excluding zones because they could play an important role in the transfer of airflow from one part of the building to another and so could have a significant effect on the natural ventilation in included zones. For example an excluded zone could block the airflow from one included zone to another. Equally, by removing large parts of the model, you run a risk of altering the stack flow regime, neutral pressure level etc in the building airflow model.

Tip: If you need to focus on a just few zones in a large model it is usually easiest to uncheck this option at building level and include only the zone(s) of interest. Another quick way to change the include/exclude status of multiple zones in one session is to use the [Model data grid edit](#) tool.

See also the [Activity data templates and time schedules](#) tutorial

Include zone in Radiance daylighting calculations

Zones which are not regularly occupied, or which for any other reason should not be included, can be excluded from daylighting calculations by unchecking this option. This option can be used when carrying out a LEED, BREEAM or Green Star daylighting credit calculation to avoid including zones that are not regularly occupied in the building assessment.

From the LEED v3 documentation:

Regularly occupied spaces in commercial buildings are areas where people sit or stand as they work. In residential applications these spaces include all living and family rooms and exclude bathrooms, closets, or other storage or utility areas. In schools, they are areas where students, teachers, or administrators are seated or standing as they work or study.

Floor Areas And Volumes

[Activity tab](#) in model data at zone and building levels only

When viewed at zone level the data on this tab refers to the current zone and when viewed at building level the data refers to the whole building. With one unusual [exception](#), all data under this heading is read-only.

Building Level

Building rotation

This is the rotation of the building relative to the site in degrees. It is available at building level only and will be zero in most cases.

Occupied floor area

The floor area of occupied zones (in m2 or ft2). This is the sum of the floor areas for zones having **1-Standard** [Zone type](#).

Occupied volume

The volume of occupied zones (in m3 or ft3). This is the sum of the zone volumes for zones having **1-Standard** [Zone type](#).

Unoccupied floor area

The floor area of unoccupied zones (in m2 or ft2). This is the sum of the floor areas for zones *not* having **1-Standard** [Zone type](#).

Unoccupied volume

The volume of unoccupied zones (in m3 or ft3). This is the sum of the volume of zones *not* having **1-Standard** [Zone type](#).

Note: The zone floor areas are calculated based on the selected [Zone floor area calculation method](#). They are not necessarily simply the sum of the floor surface areas listed in the Navigator. Likewise zone volumes are based on the [Zone volume calculation method](#).

Tip: To ensure you are viewing the most up to date building areas and volumes you can refresh the navigator using the rightmost icon at the top of the navigator panel.

Zone Level

Floor area

The floor area of the zone (in m2 or ft2). It cannot be edited.

Zone volume

The volume of the zone (in m3 or ft3). For normal closed manifold zones the zone volume is calculated from the zone geometry based on the [Zone volume calculation method](#). For [open manifold](#) zones the zone volume data comes initially from the BIM software but it can be overwritten here if required.

Inner surface mode

The Inner surface mode is a read-only value, visible at zone level only, indicating how the zone inner surfaces, and hence the zone floor area and volume, have been derived. It can have one of 4 values:

- **Deflation**, where finite thicknesses have been defined for at least one element surrounding the zone and the inner volume has been successfully created by deflating the parent zone. Volumes and surface areas are obtained from the inner zone geometry. This is the most accurate method.
- **Approximate**, the same as Deflation above but the inner volume fails to be created for one of a number of technical reasons (vertices having more than three surfaces associated with them etc.). In this case zone volume and surface areas are calculated using approximate methods.
- **Coincident** where all zone surfaces have zero thickness and so the inner volume coincides with the parent zone. In this case volumes and surface areas are obtained from the outer zone geometry.
- **Open manifold** for zones in [open manifold](#) blocks loaded from gbXML. In this case all zone surfaces have zero thickness and the surface areas are calculated from the parent zone surfaces. Because the zones are open-manifold their volumes cannot be calculated from the surface geometry and instead are read directly from the gbXML file and stored with the zone data. Open-manifold **Zone volume** settings can be overwritten by the user if required as described above.

Occupancy

[Activity tab](#) in model data

The Occupancy model data defines the number people in the space and the times of occupancy. This data is used in Simulations and Cooling design calculations together with the Metabolic heat output of the occupants and [Holidays](#) to calculate the heat input to the building.

Occupancy method

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for occupancy here on the Activity tab. Choose from the options:

- **1-People/area** - the default option where occupancy is defined as occupancy density (in people / m2 or people / ft2).
- **2-Area per person** - is sometimes preferred as an inverse occupancy density. Note that when switching between this option and occupancy density the definitions on the Activity tab zone level are translated accordingly. This is not the case when the number of people option below is selected.
- **3-Number of people** - used when detailed zone by zone survey or design data is available. Unless you need to enter specific known occupancy gains zone by zone, this option is best avoided as it increases the amount of work involved

Note: When using the **3-Number of people** option, the number of people in each room is entered zone by zone as values inherited from building and block levels will typically not be correct.

Depending on the Occupancy method selected either on model options or above, the occupancy gains can be defined in one of 3 ways, as **Occupancy density**, **Floor area per person** or **Number of people** as described below.

Occupancy density

When the [Occupancy method](#) is set to **1-Occupancy density** you can set the number of people per unit floor area. It is usually most convenient to load this data from the Activity template.

Floor area per person

When the [Occupancy method](#) is set to **2-Area per person** you can set the floor area per person, i.e. the reciprocal of the occupancy density above. You must check the **Occupied** checkbox first.

Number of people

When the [Occupancy method](#) is set to **3-Number of people** you can enter the number of people in the zone directly. In this case note that the value entered at block and building level does not normally inherit very effectively, especially in buildings with zones of very different floor areas. In this case enter the number of people for the most common type of zone at building level. Unless you need to enter specific numbers of people in each zone this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Radiant fraction

The radiant fraction of occupant heat emissions is hard set to 0.3.

Timing

The way that Occupancy is scheduled depends on the [Timing](#) model data option as described below.

Typical workday timing model option

When the [Typical workday](#) Timing model option is set, the occupancy times are controlled by setting **On** and **Off** values and the number of days in the working week.

In above example there are 0.02 people per m2 between 8am and 6pm and there are no people outside these times and at weekends.

Note: The Occupancy **Days / week** is set at the building level only and is used for all other Typical workday schedules in the model apart from Mechanical ventilation, and Heating and Cooling operation which have their own Days / week data. Valid values are 1-7.

Schedule timing model option

When the Schedule [Timing](#) model option is set, the occupancy times are controlled by a [Schedule](#). The metabolic gains for the zone are multiplied by the value of the Schedule at each time step in the simulation so you can define periods of part-occupancy using Schedule values less than 1. Use values of 0 to indicate that the space is unoccupied.

Occupancy	
Occupancy density (people/m2)	0.0200
Schedule	TM59_Kitchen_Occ

In above example number of people per m2 is calculated as $0.02 \times \text{Schedule value}$.

Occupancy latent gains

When the [Gain definition level](#) option is set to **2-Zone by zone in model data**, select the Occupancy latent gains method. There are 2 ways for the sensible-latent split of occupancy gains to be defined:

- **1-Dynamic calculation** - where the latent fraction of occupancy gains is calculated within EnergyPlus at runtime based on internal temperatures and metabolic rate. In this case the ratio of sensible to total occupancy gain will reduce as the internal temperature in the zone increases and at temperatures much above 30°C all of the occupancy gain will be latent (occupants sweating).
- **2-Fixed fraction** - where the latent fraction of occupancy gains is constant regardless of internal conditions and defined on the Activity tab (below).

Note: The total occupancy gain (sensible + latent) is not affected by this option, only the split of sensible vs latent gain.

Latent fraction

Occupancy latent gains account for moisture from people in the building due to both perspiration (sweating) and from exhaled moisture. The way that latent gains are calculated depends on the [Occupancy latent gains](#) model option.

When this option is set to **2-Fixed fraction** then you can enter the latent fraction here. A typical default value is 0.5. Alternatively if this setting is left as the default **1-Dynamic calculation** option then the latent fraction is calculated within EnergyPlus at runtime based on internal temperatures and metabolic rate and no additional setting is required here.

Metabolic

Select the level of activity by selecting a [metabolic rate](#) component based on the level of activity of people using the space.

The metabolic rate determines the amount of heat gain per person in the zone *under design conditions*. This value is modified during simulations based on a correlation to account for variations in space temperature. *This should be borne in mind when analysing occupant sensible heat output in the Cooling design and Simulation results screens.* Metabolic rate has units Watts per person and represents the total heat gain per person including convective, radiant, and latent heat. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Then, the sensible gain is divided into radiant and convective portions.

Metabolic rate data can be found in the ASHRAE Handbook of Fundamentals and in CIBSE Guide A.

DesignBuilder default metabolic data is derived from the ASHRAE values and is for adult males having typical surface area of 1.8m². For women multiply the adult male value by 0.85 and for children multiply by 0.75.

The **metabolic factor** accounts for people of various sizes. Enter 1.00 for men, 0.85 for women, 0.75 for children or you can use an average value if there is a mix of sizes.

Note: If the [Occupancy latent gains](#) model option is set to **Dynamic calculation** then the sensible/latent split for occupancy gains is affected by the internal temperature and relative humidity. With high internal temperatures, people cool themselves largely by evaporation (sweating) and sensible occupancy gains can be very low or even zero as the internal temperature approaches that of the human body.

Background

Heat is generated in the human body by oxidation at a rate called the metabolic rate. This heat is dissipated from the body surface and respiratory tract by a combination of radiation, convection and evaporation. The relative proportions of sensible and latent heat from people is a complex function of the metabolic rate and the environmental conditions.

EnergyPlus uses a polynomial function to divide the heat gain into sensible and latent portions. More details can be found in the EnergyPlus EngineeringDoc.pdf documentation.

CO2 generation rate

Enter the carbon dioxide generation rate per person in m3/s-W or (ft3/min)/(Btu/hr). The total carbon dioxide generation rate for the zone is:

Number of People * People Schedule * People Activity * Carbon Dioxide Generation Rate.

The default value is 3.82E-8 m3/s-W (obtained from ASHRAE Standard 62.1-2007 value at 0.0084 cfm/met/person over the general adult population). The maximum value can be 10 times the default value.

Clothing

Clothing schedule definition

You can define the clothing levels of the occupants using two Clothing schedule definition options:

- **1-Generic summer and winter clothing** where the level of clothing insulation is entered as 2 fixed values one for Summer and the other for Winter. Start and end days for each period are defined under the "Time and daylight saving" on page 316 header at site level.
- **2-Schedule based clothing** which allows application of a custom schedule to define level of clothing insulation

This data is used when generating [comfort output](#).

Clothing reduces the body's heat loss and is classified according to its insulation value. The unit normally used for measuring clothing's insulation is the Clo unit. The more technical unit is m²C/W is also used frequently (1 Clo = 0.155 m²C/W). The Clo value can be calculated by adding the Clo value of each individual garment. The insulation value for individual garments can be found in ISO 7730.

Clo-Values for Different Items of Clothing and Ensembles

Clothing	Clo-Value
Naked	0.0
Briefs	0.06
T-shirt	0.09
Bra and panties	0.05
Long underwear	
upper	0.35
lower	0.35
Shirt	
White, short sleeve	0.14
heavy, long sleeve	0.29
Add 5% for tie or turtleneck	

Skirt	0.22-0.70
Trousers	0.26-0.32
Sweater	0.20-0.37
Socks	0.04-0.10
Light summer outfit	0.3
Working clothes	0.8
Typical indoor winter clothing combination	1.0
Heavy business suit	1.5

Note 1: Clo-values are additive, so one can calculate the clo-value for a person wearing a T-shirt and light socks $(0.09 + 0.04) = 0.13$. (Adapted from ASHRAE Fundamentals and "Technical Review of Thermal Comfort," Bruel and Kjaer, No. 2, 1982.)

Note 2: For equatorial regions where there is no clear 'summer/winter' weather pattern you should generally use a **2-Schedule based clothing** definition and adjust the clothing schedule values.

Comfort Radiant Temperature Calculation

This field specifies the type of Mean Radiant Temperature (MRT) calculation the user wishes to use for the thermal comfort model. There are currently two options:

- **1-Zone averaged** where the standard MRT is used in comfort calculations.
- **2-Surface with largest window** which calculates the radiant temperature for a person close to the largest window in each zone. The MRT used in the thermal comfort calculations in this case is actually the average of the inside surface temperature of the largest window and the zone averaged MRT. The surface temperature alone is not used because the maximum view factor from a person to any flat surface is roughly 0.5. Actually the largest window surface gets slightly more weighting than 50% since the surface selected is still a part of the zone average MRT calculation. This simplification is made to avoid the need to specify view factors and the exact location of the person. If a zone has no windows then the **1-Zone averaged** option is used instead.

Note: This selection only affects comfort calculations and will not affect the [Radiant Temperature](#) reported by DesignBuilder which remains a zone-averaged value regardless.

Air Velocity

Air velocity schedule

The [thermal comfort calculations](#) carried out by EnergyPlus to obtain the [comfort outputs](#) require the velocity of the air close to the occupants .

You can select a schedule for each zone to define the time-varying velocity of the air in the space in m/s. The default schedule gives a constant air velocity of 0.137 m/s, but higher values might be appropriate for rooms with mixing fans or high volumes of HVAC air delivery, for example.

Note: For TM59 simulations you should set the air velocity to 0.1 m/s.

Contaminant Generation And Removal

[Activity tab](#) in model data

DesignBuilder offers 4 different ways to model contaminant generation and removal within each zone of the building. EnergyPlus allows only one type of contaminant to be modelled in a simulation (in addition to CO2 which is handled separately).

Note: The [Simulate contaminant concentration](#) site level option must be selected for any of the zone settings to take effect in the simulation and actually generate/remove contaminants.

Tip: The results of the contaminant simulation are not displayed in the built in results on the Simulation screen, but the zone air contaminant concentration for each zone can be viewed when using the [Results Viewer](#).

Contaminant generation/removal

Check this checkbox if you would like to model contaminant generation and/or removal for the current zone. When this option is checked the rest of the data described below becomes available for editing.

Contaminant simulation method

The contaminant simulation methods available for selection are:

- **1-Constant** where contaminant is generated/removed at a constant design rate multiplied by a time-varying schedule
- **2-Cutoff model** where the contaminant generation rate is based on the "cutoff concentration" model
- **3-Decay source** where the contaminant generation rate is based on the "decay source" model
- **4-Deposition rate sink** where the contaminant removal from a zone stops when the sink concentration level is higher than the zone air concentration level.

Different **Contaminant simulation method** settings can be made in each zone.

Constant

The **1-Constant** option allows you to specify the generic contaminant generation rate and removal rate coefficient in the zone. The associated fraction schedules allow the magnitude of sources and sinks to vary with time. The object is equivalent to the combination of the constant coefficient model and the burst source model defined in the sources and sinks element types of CONTAM 3.0.

The basic equation used to calculate generic contaminant source and sink for the constant model is given below:

$$S_f(t) = G_f(t) * F_G - R_f(t)C_f(t) * 1.0E - 6 * F_R$$

where:

S_f = Contaminant generic contaminant source strength [m3/s]
 G_f = Generic contaminant generation rate [m3/s]
 F_G = Fraction value from the source fraction schedule at a given time [dimensionless]
 R_f = Generic contaminant effective removal rate [m3/s]
 F_R = Fraction value from the sink fraction schedule at a given time [dimensionless]
 C_f = Generic contaminant concentration value at a given previous time step [ppm]

Design generation rate

Enter the full contaminant design generation rate (in m3/s or ft3/min). The design generation rate is the maximum *volume* of generic contaminant expected at design conditions. The design value is modified by the schedule fraction in the Generation schedule described below for each timestep in the simulation.

Note: When only the *mass* generation rate is available, the rate must be converted to a volume flow rate. In this case, use the mass flow rate divided by the vapour density of the generic contaminant.

Generation schedule

Select the schedule that modifies the maximum design generation rate (G_i). This fraction between 0.0 and 1.0 is noted as F_G in the above equation.

Design removal coefficient

This setting defines the full volumetric contaminant design removal coefficient (in m³/s or ft³/min). The design removal rate is the maximum amount of generic contaminant expected at design conditions times the generic contaminant concentration in the same zone. The design value is modified by the schedule fraction in the Removal schedule described below.

Removal schedule

Select the schedule that modifies the maximum design generation rate (R_i). This fraction between 0.0 and 1.0 is noted as F_R in the above equation.

Cutoff Model

The **2-Cutoff model** option allows the contaminant generation rate to be specified based on the cutoff concentration model. The basic equation used to calculate generic contaminant source for the pressure driven constant model is given below:

$$S_f(t) = \begin{cases} G_f(t) * F_G * \left(1 - \frac{C_f(t)}{C_{cutoff}}\right) & C_f < C_{cutoff} \\ 0 & C_f \geq C_{cutoff} \end{cases}$$

where:

S_f = Generic contaminant source strength [m³/s]

G_f = Generic contaminant generation rate [m³/s]

F_G = Fraction value from the source fraction schedule at a given time [dimensionless]

C_{cutoff} = Cutoff concentration at which emission ceases [ppm]

C_f = Generic contaminant concentration value at a given previous time step [ppm]

Maximum generation rate

Enter the maximum contaminant design generation rate (in m³/s or ft³/min). The design generation rate is the maximum amount of generic contaminant expected at design conditions. The design value is modified by the Generation schedule fraction (below).

Note: When the *mass* generation rate is available, the rate must be converted to a volume flow rate. Use the mass flow rate divided by the vapour density of the generic contaminant.

Generation schedule

Select the schedule that modifies the maximum design generation rate (G_i). This fraction between 0.0 and 1.0 is noted as F_G in the above equation.

Cutoff concentration

Enter the contaminant cutoff concentration level where the source ceases its emission in ppm.

Decay Source

The **3-Decay source** option allows you to specify the contaminant generation rate based on the decay source model. The basic equation used to calculate generic contaminant source for the decay source model is given below:

$$S_f(t) = G_f(t)F_G \exp(-t/t_c)$$

where:

S_f = Generic contaminant source strength [m3/s]

G_f = Initial generic contaminant generation rate [m3/s]

F_G = Fraction value from the source fraction schedule at a given time [dimensionless]

t = Time since the start of emission [second]

t_c = Decay time constant [second]

Initial emission rate

Enter the initial generic contaminant design emission rate (in m3/s in ft3/min). The generation is controlled by a schedule, as defined in the next field. Contaminant emission begins when the schedule changes from a zero to a non-zero value (between zero and one). The initial emission rate is equal to the schedule value times the initial generation rate.

Schedule

Select the schedule that modifies the maximum design emission rate (G_f). This fraction between 0.0 and 1.0 is noted as F_G in the above equation. When the value is equal to 1, the generation rate is used and time is reset to zero. When the value is equal to zero, the schedule value is ignored in the equation.

Decay time constant

The decay time constant (in s) the time at which the generation rate reaches 0.37 of the original rate.

Note: The variable t , time since the start of emission, will be reset to zero, when a new run period starts, or the generation schedule value is equal to zero.

Deposition Rate Sink

The **4-Deposition rate sink** option allows you to specify the generic contaminant removal rate from a zone. The object is equivalent to the deposition rate sink model defined in CONTAM 3.0 sources and sinks element types.

The deposition rate model provides for the input of a sinks' characteristic in the familiar term of deposition rate in a zone. The removal stops when the sink concentration level is higher than the zone air concentration level. The deposition rate model equation is:

$$S_f(t) = k_d V_z * C_f(t) * 1.0E - 6 * F_R m$$

Where:

$S_f(t)$ = Removal rate at time t [m3/s]

k_d = Deposition rate [1/T]

V_z = Zone volume [m3]

m = Element multiplier [dimensionless]

$C_f(t)$ = Concentration of generic contaminant at the previous time step [ppm]

F_R = Schedule or control signal value at time t [dimensionless]

Deposition Rate

This field specifies the deposition rate to the zone (in m3/s or ft3/min).

Schedule

Select the schedule that modifies the maximum design removal rate (S_i). This fraction between 0.0 and 1.0 is noted as F_R in the above equation.

Holidays

[Activity tab](#) in model data (building level only)

You can define the dates of holidays to include the effect of building shutdown during certain periods of the year. Do this by selecting the Holidays option under the Holidays header on the Activity tab **at building level**. Holidays defined at building level in this way are used for the whole simulation. The holiday data is used for Simulations only (not Heating/Cooling Design Calculations) and allows you to set the [Holiday Schedule](#) and the number of days of holiday per year. The [possible holiday dates](#) are defined in the Holiday schedule and the actual holidays to be used in the simulation are selected from the top of the list based on the **Holidays per year** data entered.

Note that you must have at least as many days defined in the holiday schedules as you request here. If there are insufficient holidays in the holiday schedule you will receive an error message to this effect prior to a simulation.

Holidays

☒ Holidays

Holidays per year 5

 Holiday schedule Typical UK

With the data in the above screenshot there will be 5 holidays and the dates are given by the first 5 holiday dates set in the 'Typical UK' Holiday schedule.

See also the [Timings, schedules and profiles](#) tutorial

The way holiday definition works depends on the [Timing](#) model option:

Compact Schedules

When the [Timing](#) model option is Schedules you can use [Compact schedules](#) to define holiday dates and schedule values. The value of Compact schedule output during holidays can be defined explicitly using the Holidays day type following **For**:

For example:

```
SCHEDULE:COMPACT,  
Bedroom_Cool,  
Temperature,  
Through: 31 Dec,  
For: Weekdays SummerDesignDay WinterDesignDay,  
Until: 05:00, 0.5,  
Until: 09:00, 1,  
Until: 24:00, 0.5,  
For: Weekends,
```

```

Until: 05:00, 0.5,
Until: 24:00, 1,
For: Holidays AllOtherdays,
Until: 24:00, 0;

```

The Holiday data in this [Compact schedule](#) indicates that the cooling is switched off on holidays.

7/12 Schedules

Holiday operation is not defined explicitly and holidays use the same data as Sundays

Typical Workday

Holidays use the same data as Sundays

Environmental Control

[Activity tab](#) in model data

The heating and cooling setpoint temperatures, minimum fresh air per person and illuminance requirements are related to the Activity or Usage of the zone and are accessed by opening the Environmental Comfort group header.

Heating Setpoint Temperatures

Heating setpoint temperature

Defines the ideal temperature (i.e. the setting of the heating thermostat) in the space when heating is required. Its meaning depends on the [Temperature control](#) calculation option. When using **1-Air temperature** control the **Heating setpoint temperature** corresponds to the air temperature in the space and when it is set to set to **2-Operative temperature** it is the operative temperature $(MAT+MRT)/2$.

Heating setback setpoint temperature

Some buildings require a low level of heating during unoccupied periods to avoid condensation/frost damage or to prevent the building becoming too cold and to reduce peak heating requirements at startup. Enter the setpoint temperature to be used at night-time, weekends and other holidays during the heating season. Its meaning depends on the [Temperature control](#) calculation option (above).

Note: when using the **Typical workday** timing option, this setback temperature set point is only applied during unoccupied periods such as night-time and holidays during the heating season. It is not applied during the summer (if heating is switched off during the summer.)

Note: if the setback temperature set does not appear to affect results when using a [Compact schedule](#), this may be because the **Zone setpoint heating schedule** selected uses only 0 and 1, not the 0.5 required to access setback temperature. See [Defining setpoint temperature schedules](#) for more on this.

Cooling Setpoint Temperatures

Cooling setpoint temperature

Defines the ideal temperature (i.e. the setting of the cooling thermostat) in the space when cooling is required. Its meaning depends on the [Temperature control](#) calculation option. When using **1-Air temperature** control the **Cooling setpoint temperature** corresponds to the air temperature in the space and when it is set to set to **2-Operative temperature** it is the operative temperature $(MAT+MRT)/2$.

Note: the cooling setpoint temperature must be higher than the heating setpoint temperature.

Cooling setback setpoint temperature

Some buildings require a low level of cooling during unoccupied periods to prevent the building becoming too hot and to reduce the startup cooling load the next morning. Enter the setpoint temperature to be used at night-time, weekends and other holidays during the cooling season. Its meaning depends on the [Temperature control](#) calculation option (above).

Note: when using the **Typical workday** timing option, this setback temperature set point is only applied during unoccupied periods such as night-time and holidays during the cooling season. It is not applied during the winter (if cooling is switched off during the winter.)

Note: if the setback temperature set does not appear to affect results when using a [Compact schedule](#), this may be because the **Zone setpoint cooling schedule** selected uses only 0 and 1, not the 0.5 required to access setback temperature. See [Defining setpoint temperature schedules](#) for more on this.

Humidity Setpoint Temperatures

When using some Simple and Detailed HVAC systems you can control humidity. In the case of AHU-type systems the humidity in a control zone is controlled. The zone humidification and dehumidification setpoints can be defined here. Note that for systems without humidity control these setpoints are ignored.

RH Humidification setpoint

The zone humidistat relative humidity setpoint for humidification (0 to 100%).

RH Dehumidification setpoint

The zone humidistat relative humidity setpoint for dehumidification (0 to 100%).

Comfort PMV Setpoints

When using Detailed HVAC and the [Temperature control](#) option is set to **4-Fanger comfort** and the [Detailed HVAC Activity data](#) option is set to **1-Simple HVAC**, the zones are heated and cooled using the Fanger PMV heating and cooling comfort setpoints defined below as setpoints. When using the **2-Detailed HVAC** [Detailed HVAC Activity data](#) option, schedules of Fanger PMV comfort are defined on the [HVAC zone](#) dialog instead.

The [Thermal comfort calculator tool](#) can be used to derive PMV values based on the known environmental conditions.

Heating PMV setpoint

The PMV used as the heating setpoint when the heating operation schedule on the HVAC tab has value 1.

Heating PMV setback

The PMV used as the heating setback when the heating operation schedule on the HVAC tab has value 0.5.

Cooling PMV setpoint

The PMV used as the cooling setpoint when the cooling operation schedule on the HVAC tab has value 1.

Cooling PMV setback

The PMV used as the cooling setback when the cooling operation schedule on the HVAC tab has value 0.5.

Ventilation Setpoint Temperatures

Natural ventilation indoor min temperature control

If you wish to use natural ventilation to cool the building/block/zone down to a particular setpoint temperature and then shut off when the temperature goes below that setpoint then check this box. This allows you to define the **Natural ventilation cooling setpoint temperature** described below.

Natural ventilation min temperature control applies to both Calculated and Scheduled natural ventilation.

Tip: To ensure that natural ventilation occurs regardless of internal temperature (e.g. to use nat vent provide fresh air) then uncheck this option.

Min temperature definition

There are 2 ways to define the Natural ventilation min temperature:

- **1-By value** - use this option when the setpoint does not change with time in which case you can enter a fixed setpoint temperature.
- **2-By schedule** - use this option when the setpoint changes with time in which case you can select a schedule of time-varying temperature setpoints.

Natural ventilation min temperature

This is the fixed indoor temperature (in °C or °F) below which ventilation is shut off. The control is visible when the **1-By value** option is selected for **Min temperature definition**. It can be thought of as the cooling setpoint temperature which controls the activation of natural ventilation. If the inside air temperature is greater than this setpoint temperature (and the natural ventilation operation schedule is on) then [natural ventilation](#) can take place. The way this works depends on the [Natural ventilation model option](#).

Note that when using the [Calculated natural ventilation](#) model option windows and vents are only opened when:

- The inside air temperature is above this cooling setpoint temperature, and
- The inside air temperature is greater than the outside air temperature, and
- The operation schedule allows ventilation.

Also, the data under the [Calculated Natural Ventilation](#) header on the [Advanced tab](#) of the [Model Options](#) dialog can modify ventilation control behaviour.

When using the [Scheduled natural ventilation](#) model option the **Natural ventilation delta T** (below) can prevent natural ventilation from occurring if the outside air temperature is too high.

Natural ventilation min temperature schedule

The schedule which defines the time-varying indoor temperature (in °C) below which ventilation is shut off. The control is visible when the **2-By schedule** option is selected for **Min temperature definition**. It can be thought of as the time-varying cooling setpoint temperature which controls the activation of natural ventilation.

See also [Defining setpoint temperature schedules](#).

Natural ventilation indoor max temperature control

If there is a maximum zone air temperature above which the natural ventilation should shut off then check this option. This upper temperature limit is intended to avoid overheating a space and/or unnecessarily increasing cooling loads.

Normally when using natural ventilation for cooling this option will be left unchecked as it would be unusual to place an upper limit on the zone temperature for operation of such a system.

Indoor max temperature control option is used only with Scheduled natural ventilation and is not available for Calculated natural ventilation.

Max temperature definition

There are 2 ways to define the Natural ventilation max temperature:

- **1-By value** - use this option when the setpoint does not change with time in which case you can enter a fixed setpoint temperature.
- **2-By schedule** - use this option when the setpoint changes with time in which case you can select a schedule of time-varying temperature setpoints.

Natural ventilation max temperature

This is the fixed indoor temperature (in °C or °F) above which ventilation is shut off. The control is visible when the **1-By value** option is selected for **Max temperature definition**.

Natural ventilation max temperature schedule

The schedule which defines the time-varying indoor temperature (in °C) above which ventilation is shut off. The control is visible when the **2-By schedule** option is selected for **Max temperature definition**.

See also [Defining setpoint temperature schedules](#).

Mechanical ventilation control

The mechanical ventilation cooling setpoint temperature and delta T values described below control the activation of mechanical ventilation when using [Simple HVAC](#) together with the **1-Room ventilation Mechanical ventilation method**.

Mechanical ventilation cooling setpoint temperature

The mechanical ventilation cooling setpoint temperature controls the activation of mechanical ventilation when using [Simple HVAC](#) together with the **1-Room ventilation Mechanical ventilation method**. If the inside air temperature is greater than this setpoint temperature (and the mechanical ventilation operation schedule is on) then mechanical ventilation can take place.

This data and the corresponding delta T data described below are not used in simulations when working with the Simple HVAC **2-Ideal loads** option or with Detailed HVAC and are never used in Heating and Cooling design calculations.

Mechanical ventilation max natural ventilation in-out delta T

The mechanical ventilation Max int-out temp difference is used for [Scheduled mechanical ventilation](#) only and is the temperature difference between the indoor and outdoor air dry bulb temperatures below which ventilation is shut off. This is to allow ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. It is not related to preventing drafts.

For example, if you specify a maximum delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry bulb temperature is less than 2°C cooler or warmer than the indoor dry bulb temperature, then ventilation is automatically turned off. The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature. The Delta Temperature control works in the code in the following way:

if $(IndoorTemp - OutdoorTemp) < \text{Max ventilation in-out delta } T$ then ventilation is **not allowed**.

For example:

Value of Mechanical ventilation Max in-out delta T	Effect
0	Mechanical ventilation only operates when $OutdoorTemp < IndoorTemp$
-50	Mechanical ventilation unrestricted by Inside-Outside delta T
2	Mechanical ventilation only operates when $OutdoorTemp + 2 < IndoorTemp$

Tip: Enter a large negative number to allow ventilation even if the outdoor temperature is greater than the indoor temperature. This useful for uncontrolled mechanical ventilation or as a way to estimate the effect of required ventilation air for load calculations.

See also [Defining setpoint temperature schedules](#).

Minimum Fresh Air

Minimum fresh air data is defined on the Activity tab because the fresh air requirement of the people in the zone depends on the activity (use) of the space.

Fresh air

The **Minimum fresh air per person** defines the fresh air requirements of each person in the zone and is used to generate appropriate mechanical outside air distribution rates when the mechanical ventilation [Outside air definition methods](#) on the [HVAC tab](#) is set to any of:

- **2-Min fresh air per person** where the fresh air flow rate is calculated as the **Fresh air (l/s/person)** x People / m² x Zone floor area (m²)
- **4-Min fresh air (Sum per person + per area)** where the fresh air flow rate is the sum of 'per person' and 'per area' fresh air requirements
- **5-Min fresh air (Max per person and per area)** where the fresh air flow rate based on 'per person' is compared with 'per area' and the maximum is used.

This data is also used to calculate *natural* ventilation outside air flow rates into the zone when the natural ventilation [Flow type](#) on the HVAC tab is set to **2-Min fresh air per person**.

Mech vent per area

The **Mech vent per area** data defines the fresh air requirements of the zone per floor area and is used to calculate mechanical outside air distribution rates when the mechanical ventilation [Outside air definition methods](#) on the [HVAC tab](#) is set to any of:

- **3-Min fresh air (Per area)**, where the fresh air flow rate is calculated as the **Mech vent per floor area** (l/s/m²) x Zone floor area (m²)
- **4-Min fresh air (Sum per person + per area)**,

- **5-Min fresh air (Max per person and per area).**

This data is not currently used for natural ventilation and is only used if one of the above mechanical ventilation [Outside air definition methods](#) has been used.

CO2/Contaminant Setpoints

If the zone has its fresh air delivery controlled using the **4-IAQP** DCV method and the **1-Simple HVAC Detailed HVAC Activity data** model option is set then you must enter the CO2 setpoint and minimum setting here on the Activity tab. Likewise if the **7-IAQP generic contaminant** option is selected then the generic contaminant setpoint and minimum setting must be entered here.

If the **2-Detailed HVAC Detailed HVAC Activity data** model option is set then this data is entered on the [HVAC Zone dialog](#) using schedules.

CO2 concentration setpoint

Enter the constant CO2 concentration setpoint in ppm.

Min CO2 concentration

Enter the minimum allowed CO2 concentration in ppm.

Max CO2 concentration

Enter the maximum allowed CO2 concentration in ppm. It is used to calculate design CO2 concentration level in the proportional ventilation control.

The **Min CO2 concentration** and **Max CO2 concentration** settings are only used when the [System outdoor air method](#) is set to one of:

- **5-Proportional control based on design occupancy**
- **6-Proportional control based on occupancy schedule**
- **9-Proportional control based on design outdoor air rate**

Generic contaminant concentration setpoint

Enter the constant generic contaminant concentration setpoint in ppm. The value should be between 0 and 1.

Lighting

Target illuminance

The desired lighting level (in lux) at the first daylighting sensor. This is also the lighting level that would be produced at this sensor position at night if the overhead electric [General lighting](#) were operating at full input power. Recommended values depend on type of activity; they may be found, for example, in the Lighting Handbook of the Illuminating Engineering Society of North America and in CIBSE A Guide. A typical value for general office work (excluding computer terminals) is 500 lux.

Default display lighting density

This data allows you to define the typical density of display lighting for the activity. The value is used as a default on the Lighting tab for the Task and Display lighting density to ensure that the display lighting density is appropriate for the activity of the zone.

When the [Lighting gain units](#) model option is set to **1-Power density** and a lighting template is loaded, this value is copied directly from the Activity tab to the corresponding [Task and Display Gain](#) value on the Lighting tab.

The Default display lighting density comes from the activity rather than from the lighting template because the gain is more likely to be a function of the activity than of the type of lighting system installed.

Domestic Hot Water (DHW)

[Activity tab](#) in model data

DHW Consumption rate

In DesignBuilder the amount of DHW consumed is considered to be a function of the activity in the zone. For example, there is a demand assumed to arise from the occupants of an office for activities such as washing hands and washing up cups. This demand is associated with the office rather than the toilet or tea room. Thus the demand from each space needs to be assigned to a DHW system even if the system itself is not present in the space.

The effect of hot water consumption (hot water taps, showers etc) on building energy use can be included in your thermal model by switching on [DHW](#) on the HVAC tab.

The data on this tab defines the hot water consumption rate in each zone as l/day/m² data (gal/day/ft in IP units). **The DHW consumption data is only used if DHW is selected on the HVAC tab.**

The DHW consumption rate is the amount of water used over a whole day per floor area. The consumption should be entered for the day of the year having the most consumption. For example in an office it might be the consumption over a typical work day. You should *not* enter an average rate over the year including reduced rates on weekends etc.

Note: If you have DHW consumption data in **l/person/day** format you can convert to the **l/m²-day** format used in DesignBuilder by multiplying it by [occupant density](#) (people/m²).

With Simple HVAC, the [hot water generation system](#) is defined under [DHW](#) on the HVAC tab.

Note: This DHW consumption data is also used in Detailed HVAC with the default **1-Simple HVAC Detailed HVAC Activity data** setting.

Computer Gains

[Activity tab](#) in model data

Check the **Computers > On** checkbox to model the heat emissions and fuel consumption due to computer gains and other related IT equipment in the simulation.

Units

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for internal gains here on the Activity tab. Choose from the options:

- **1-Power density** where zone equipment gains are entered as a power density, i.e. as a power per zone floor area in W/m² or W/ft². This option is usually the most convenient method for most general purpose modelling as the data is normalised by area and so can be inherited from levels above in the model hierarchy and can be effectively loaded from Activity template.
- **2-Absolute zone power** where zone equipment gains are entered as a power value in W. This option is usually used when detailed zone by zone survey or design data is available. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases

the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Gain

Set the design level of energy consumption due to computers. Depending on the [Equipment gain units](#) model option setting, the gains data is entered either as **Absolute zone power** (in W) or as **Power density** (in W/m² or W/ft²).

The fuel is assumed to be *electricity*, all gains are assumed to be emitted to the space.

Schedule

Select the schedule that governs the timing of gains in the zone. The level of gains are multiplied by the time-varying factor in this schedule to give the gain for each timestep in the simulation.

Radiant Fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of long-wave radiant heat being given off by computer equipment in a zone. The radiant fraction will be multiplied by the total energy consumed by electric equipment and (1-Fraction lost) to give the amount of long wavelength radiation gain from computer equipment in a zone. A value of zero means that the heat gain is entirely convective in which case all the heat is transferred to the air node in simulations. A value of 1 means that the gain is entirely radiative in which case all the heat is distributed to the inside surfaces. A typical value is somewhere between 0.1 and 0.2.

If the [Internal gains operate with occupancy](#) model option is not selected you can also set the operation schedule.

Office Equipment Gains

[Activity tab](#) in model data

Check the **Office Equipment > On** checkbox to include office equipment internal gains in the simulation.

Units

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for internal gains here on the Activity tab. Choose from the options:

- **1-Power density** where zone equipment gains are entered as a power density, i.e. as a power per zone floor area in W/m² or W/ft². This option is usually the most convenient method for most general purpose modelling as the data is normalised by area and so can be inherited from levels above in the model hierarchy and can be effectively loaded from Activity template.
- **2-Absolute zone power** where zone equipment gains are entered as a power value in W. This option is usually used when detailed zone by zone survey or design data is available. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Gain

Set the design level of energy consumption due to office equipment. Depending on the [Equipment gain units](#) model option setting, the gains data is entered either as **Absolute zone power** (in W) or as **Power density** (in W/m² or W/ft²).

The fuel is assumed to be *electricity*, all gains are assumed to be emitted to the space.

Schedule

Select the schedule that governs the timing of gains in the zone. The level of gains are multiplied by the time-varying factor in this schedule to give the gain for each timestep in the simulation.

Radiant Fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of long-wave radiant heat being given off by office equipment in a zone. The radiant fraction will be multiplied by the total energy consumed by electric equipment to give the amount of long wavelength radiation gain from office equipment in a zone.

A value of zero means that the heat gain is entirely convective in which case all the heat is transferred to the air node in simulations. A value of 1 means that the gain is entirely radiative in which case all the heat is distributed to the inside surfaces. a typical value is somewhere between 0.1 and 0.4.

If the [Internal gains operate with occupancy](#) model option is not selected you can also set the operation schedule.

Miscellaneous Gains

[Activity tab](#) in model data

Check the **Miscellaneous > On** checkbox to include any Miscellaneous gains in the simulation.

Units

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for internal gains here on the Activity tab. Choose from the options:

- **1-Power density** where zone equipment gains are entered as a power density, i.e. as a power per zone floor area in W/m² or W/ft². This option is usually the most convenient method for most general purpose modelling as the data is normalised by area and so can be inherited from levels above in the model hierarchy and can be effectively loaded from Activity template.
- **2-Absolute zone power** where zone equipment gains are entered as a power value in W. This option is usually used when detailed zone by zone survey or design data is available. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Gain

Set the design level of energy consumption due to miscellaneous equipment. The actual heat gain to the space may be reduced through the **Fraction lost** data (below).

Depending on the [Equipment gain units](#) model option setting, the gains data is entered either as **Absolute zone power** in W or as **Power density** in W/m² or W/ft².

Schedule

Select the schedule that governs the timing of gains in the zone. The level of gains are multiplied by the time-varying factor in this schedule to give the gain for each timestep in the simulation.

Fuel

The fuel can be selected from a drop down list. Note that these fuels are currently mapped to a shorter list in the results as follows:

Fuel in Model Data	Mapped to Fuel in Output
--------------------	--------------------------

1-Electricity from grid	Electricity
2-Natural gas	Gas

Fraction lost

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of 'lost' heat being given off by the equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by equipment to give the amount of heat which is 'lost' and does not impact the zone energy balances. This might correspond to electrical energy converted to mechanical work or heat that is vented to the atmosphere.

Latent fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by miscellaneous equipment in a zone. The number specified in this field will be multiplied by the total energy consumed to give the amount of latent energy produced by the miscellaneous equipment. This latent energy affects the moisture balance within the zone.

Radiant Fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of long-wave radiant heat being given off by miscellaneous equipment in a zone. The radiant fraction will be multiplied by the total energy consumed by electric equipment and (1-Fraction lost) to give the amount of long wavelength radiation gain from miscellaneous equipment in a zone. A value of zero means that the heat gain is entirely convective in which case all the heat is transferred to the air node in simulations. A value of 1 means that the gain is entirely radiative in which case all the heat is distributed to the inside surfaces. a typical value is somewhere between 0.1 and 0.5.

If the [Internal gains operate with occupancy](#) model option is not selected you can also set the operation schedule.

CO2 generation rate

This numeric input field, available only when the fuel is selected as **2-Natural gas**, specifies carbon dioxide generation rate with units of m3/s-W or (ft3/min)/(Btu/hr). The default value of 0.0 assumes the equipment is fully vented to outdoors.

In the absence of better information, a value of 3.45E-8 m3/s-W can be used which assumes the equipment is not vented to outdoors. This value is converted from natural gas CO2 emission rate at 11.7 lbs CO2 per therm, the CO2 emission rate provided by U.S. Energy Information Administration. The maximum value for this input field is 3.45E-7 m3/s-W.

Calculation

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In the simulation this heat is divided into four different fractions. Three of these are given by the input fields Latent fraction, Radiant fraction and Fraction lost. The convected fraction, defined as the fraction of the heat from electric equipment convected to the zone air, is calculated by the program as:

$$F_{\text{convected}} = 1.0 - (\text{Latent fraction} + \text{Radiant fraction} + \text{Fraction lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

Catering Gains

[Activity tab](#) in model data

Check the **Catering > On** checkbox to include any cooking gains and other catering activities in the simulation.

Units

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for internal gains here on the Activity tab. Choose from the options:

- **1-Power density** where zone equipment gains are entered as a power density, i.e. as a power per zone floor area in W/m² or W/ft². This option is usually the most convenient method for most general purpose modelling as the data is normalised by area and so can be inherited from levels above in the model hierarchy and can be effectively loaded from Activity template.
- **2-Absolute zone power** where zone equipment gains are entered as a power value in W. This option is usually used when detailed zone by zone survey or design data is available. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Gain

Set the design level of energy consumption due to catering equipment. The actual heat gain to the space may be reduced through the **Fraction lost** data (below).

Depending on the [Equipment gain units](#) model option setting, the gains data is entered either as **Absolute zone power** in W or as **Power density** in W/m² or W/ft².

Schedule

Select the schedule that governs the timing of gains in the zone. The level of gains are multiplied by the time-varying factor in this schedule to give the gain for each timestep in the simulation.

Fuel

The fuel can be selected from a drop down list. Note that these fuels are currently mapped to a shorter list in the results as follows:

Fuel in Model Data	Mapped to Fuel in Output
1-Electricity from grid	Electricity
2-Natural gas	Gas

Fraction lost

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of 'lost' heat being given off by the catering equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by equipment to give the amount of heat which is 'lost' and does not impact the zone energy balances. This might correspond to cooker heat that is vented to the atmosphere through an extract hood.

Latent fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by catering equipment in a zone. The number specified in this field will be multiplied by the total energy consumed to give the amount of latent energy produced by the catering equipment. This latent energy affects the moisture balance within the zone.

Radiant fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of long-wave radiant heat being given off by catering equipment in a zone. The radiant fraction will be multiplied by the total energy consumed by electric equipment and (1-Fraction lost) to give the amount of long wavelength radiation gain from catering equipment in a zone. A value of zero means that the heat gain is entirely convective in which case all the heat is transferred to the air node in simulations. A value of 1 means that the gain is entirely radiative in which case all the heat is distributed to the inside surfaces. a typical value is somewhere between 0.1 and 0.5.

If the [Internal gains operate with occupancy](#) model option is not selected you can also set the operation schedule.

CO2 generation rate

This numeric input field, available only when the fuel is selected as **2-Natural gas**, specifies carbon dioxide generation rate with units of m3/s-W or (ft3/min)/(Btu/hr). The default value of 0.0 assumes the equipment is fully vented to outdoors.

In the absence of better information, a value of 3.45E-8 m3/s-W can be used which assumes the equipment is not vented to outdoors. This value is converted from natural gas CO2 emission rate at 11.7 lbs CO2 per therm, the CO2 emission rate provided by U.S. Energy Information Administration. The maximum value for this input field is 3.45E-7 m3/s-W.

Calculation

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In the simulation this heat is divided into four different fractions. Three of these are given by the input fields Latent fraction, Radiant fraction and Fraction lost. The convected fraction, defined as the fraction of the heat from electric equipment convected to the zone air, is calculated by the program as:

$$F_{\text{convected}} = 1.0 - (\text{Latent fraction} + \text{Radiant fraction} + \text{Fraction lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

Process Gains

[Activity tab](#) in model data

Check the **Process > On** checkbox to include any process gains in the simulation. Process gains model the heat emissions and fuel consumption due to any manufacturing or industrial process which is part of the business activity.

Units

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for internal gains here on the Activity tab. Choose from the options:

- **1-Power density** where zone equipment gains are entered as a power density, i.e. as a power per zone floor area in W/m2 or W/ft2. This option is usually the most convenient method for most general purpose modelling as the data is normalised by area and so can be inherited from levels above in the model hierarchy and can be effectively loaded from Activity template.
- **2-Absolute zone power** where zone equipment gains are entered as a power value in W. This option is usually used when detailed zone by zone survey or design data is available. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Gain

Set the design level of energy consumption due to process activity. The actual heat gain to the space may be reduced through the **Fraction lost** data (below).

Depending on the [Equipment gain units](#) model option setting, the gains data is entered either as **Absolute zone power** in W or as **Power density** (in W/m2 or W/ft2).

Tip: You can enter **negative process gains** for modelling the cooling effect from refrigeration units such as those found in supermarkets where the refrigerator doors may open and cause cool air to enter the zone. Please note that **for any such negative gains, the associated fuel consumption is not accounted for.**

This is because the EnergyPlus fuel type must be set to “None” for negative gains regardless of the fuel type actually selected in the user interface.

Schedule

Select the schedule that governs the timing of gains in the zone. The level of gains are multiplied by the time-varying factor in this schedule to give the gain for each timestep in the simulation.

Fuel

The fuel can be selected from a drop down list. Note that these fuels are currently mapped to a shorter list in the results as follows:

Fuel in Model Data	Mapped to Fuel in Output
1-Electricity from grid	Electricity
2-Natural gas	Gas

Fraction lost

This field is a decimal number between 0.0 and 1.0 and is used to characterise the amount of 'lost' heat being given off by the process equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by equipment to give the amount of heat which is 'lost' and does not impact the zone energy balances. This might correspond to electrical energy converted to mechanical work or heat that is vented to the atmosphere.

Latent fraction

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by process equipment in a zone. The number specified in this field will be multiplied by the total energy consumed to give the amount of latent energy produced by the process equipment. This latent energy affects the moisture balance within the zone.

Radiant fraction

This is a decimal number between 0.0 and 1.0 and is used to characterise the amount of long-wave radiant heat being given off by process equipment in a zone. The radiant fraction will be multiplied by the total energy consumed by electric equipment and (1-Fraction lost) to give the amount of long wavelength radiation gain from process equipment in a zone. A value of zero means that the heat gain is entirely convective in which case all the heat is transferred to the air node in simulations. A value of 1 means that the gain is entirely radiative in which case all the heat is distributed to the inside surfaces. a typical value is somewhere between 0.1 and 0.5.

If the [Internal gains operate with occupancy](#) model option is not selected you can also set the operation schedule.

CO2 generation rate

This numeric input field, available only when the fuel is selected as **2-Natural gas**, specifies carbon dioxide generation rate with units of m³/s-W or (ft³/min)/(Btu/hr). The default value of 0.0 assumes the equipment is fully vented to outdoors.

In the absence of better information, a value of 3.45E-8 m³/s-W can be used which assumes the equipment is not vented to outdoors. This value is converted from natural gas CO₂ emission rate at 11.7 lbs CO₂ per therm, the CO₂ emission rate provided by U.S. Energy Information Administration. The maximum value for this input field is 3.45E-7 m³/s-W.

Calculation

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In the simulation this heat is divided into four different fractions. Three of these are given by the input fields Latent fraction, Radiant fraction and Fraction lost. The convected fraction, defined as the fraction of the heat from electric equipment convected to the zone air, is calculated by the program as:

$$F_{\text{convected}} = 1.0 - (\text{Latent fraction} + \text{Radiant fraction} + \text{Fraction lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

Construction Model Data

Construction tab in model data

DesignBuilder uses [construction](#) components to model the conduction of heat through walls, roofs, ground and other opaque parts of the building envelope. Constructions can be selected on the Constructions model data tab to define the thermophysical and visual properties of the various internal and external surface elements in the building. From the Construction model data tab, you can access data on:

- [Construction](#)
- [Airtightness](#)
- "Construction Cost" on page 408

Open the headers to enter construction details where they are different from those loaded from the template. Any changes you make that are different from the template data originally loaded shown in bold red.

See also the [Construction data](#) and [Create and edit constructions](#) tutorials

Templates

General Construction and glazing

When you have the [General](#) Construction and glazing model option set, you can load generic Construction data by clicking on the Template option under Construction Template and then by clicking on the '...' at the right of the line (below).

When you make a selection from the list of [Construction templates](#) data from selected template is loaded to the model.

Pre-design Construction and glazing

Alternatively when you have the [Pre-design](#) Construction and glazing model option set, generic constructions can be loaded using the Insulation and Thermal mass sliders as shown below. In this case you are restricted to the 4x3 construction templates from the <System> Construction templates category identified by the combination of Insulation and Thermal mass selected on the sliders. For example in the screenshot shown below data will be loaded from the 'Energy code - Mediumweight' template.

As you change the slider settings DesignBuilder loads an appropriate set of constructions based on the rules explained below.

The various Insulation options take their insulation performance from the site level Energy code settings, which in turn default to settings based on the Region selected at the top of the Region tab.

When using the Pre-design Construction and Glazing model option ...

Tip: You can read about how to use and control these system "Early Design" Construction templates on the "Legislative Region Templates - Standard Insulation" on page 1512 help page.

Or in either case you can use the [Load data from template](#) tool.

Constructions

[Construction tab in model data](#)

From the Construction tab, you can open the group header boxes to edit detailed makeup of the construction of walls, roofs, floors, ceilings, partitions etc. used in the building.

The [default/inheritance](#) system used in DesignBuilder allows you to define building constructions quickly and easily by [loading data from templates](#) and by making global settings at building, block and zone levels.

Construction data:

- [Sub-Surface Construction](#) - construction details of sub-surfaces (opaque surfaces within surfaces)
- [Internal Thermal Mass](#) - how to define additional thermal mass
- [Adjacency](#) - defining special adjacency conditions

Note: data on the [Openings tab](#) can be used to define the layout of the facade.

View/Edit construction details

To inspect the details of a selected [construction](#), click on the icon to the left of the appropriate data entry box ([Learning mode](#) only). Alternatively double-click the icon to view/edit the data in a dialog.

Note: Please be aware that **all settings made on the Constructions Model data tab are defaults, (unless you are working at the surface level)**. Model data at the surface level (inherited from the zone above or directly set) defines the thermal and visual characteristics of the surface in the model.

Constructions Data

[Construction tab](#) in model data under [Construction header](#)

Schematic Diagram Showing Construction Locations

The schematic below shows the locations of various surface types and the constructions that will be applied to them. It also shows block and zone dimension definitions.

Note: If you are using the NCM for EPCs, Part-L/Section 6 etc calculations you should refer to the [Block and Zone Dimensions](#) page for a more detailed definition of block heights.

External walls

The external wall construction defines the construction of walls adjacent to outside. The definition of walls is given by the roof-wall transition angle model option. In cold climates this construction will generally include an insulating layer.

Below grade walls

The Below grade wall construction is used for walls that are adjacent to ground. If there are no below grade (underground) walls in the model then just ignore this data.

Flat roof

Flat roof constructions apply to external horizontal surfaces. The construction used to represent the flat roof should include any slabs, insulation and suspended ceiling layers. If there are no flat roof surfaces, just ignore this data.

Pitched roof (occupied)

The Pitched roof (occupied) construction applies to external sloped surfaces when they appear in [occupied zones](#). In cold climates this construction will generally include an insulating layer. If there are no pitched roof surfaces, just ignore this data.

The definition of 'pitched roof' is given by the roof-wall transition angle model option.

Pitched roof (unoccupied)

The Pitched roof (unoccupied) construction applies to external sloped surfaces when they appear in [Semi exterior unconditioned zones](#). This construction will generally not include any insulation layers. If there are no pitched roof surfaces, just ignore this data.

The definition of 'pitched roof' is given by the roof-wall transition angle model option.

Internal partitions

The internal partition construction defines the construction of internal partitions (walls used to divide blocks into zones) and inter-block partitions (internal walls shared with other blocks). Internal partitions are used where both zones are occupied. When one of the zones is occupied and the other is not the **Semi-exposed walls** construction data is used instead (below). If there are no partitions then this data can be ignored.

The construction for the partition should represent all the layers in the actual internal wall. The partition between the zones is represented by a single Internal partition construction and all its layers should all be defined in the same construction.

Changes in model data settings at the surface level are reflected as equivalent changes in data for the partition on the surface representing other side.

Note: this data is not available at zone level to avoid ambiguity when different settings are made in adjacent zones. Surface level partition settings are generally inherited from block level, however settings for *inter-block* partition surfaces are inherited from the building level. For details on these rules see: "Zone Level Data for Internal Surfaces" on page 700.

Semi-Exposed

Semi-exposed walls

The semi-exposed wall construction applies to walls between fully occupied zones and [Semi-exterior unconditioned zones](#). They will normally include some insulation. DesignBuilder determines which of the zones is relatively 'outside' and uses this information to correctly order the material layers in the wall. The material layer defined in the construction as being 'outermost' (first-in list) will be the one adjacent to the semi-exterior unconditioned zone. If there are no semi-exposed wall surfaces, just ignore this data.

Note: this data is not available at zone level to avoid ambiguity when different settings are made in adjacent zones. Surface level semi-exposed wall settings are generally inherited from block level, however settings for *inter-block* semi-exposed walls are inherited from the building level. For details on these rules see: "Zone Level Data for Internal Surfaces" on page 700.

Semi-exposed ceiling

The semi-exposed ceiling construction is used between occupied zones and [Semi-exterior unconditioned zones](#) (such as roofspace/attic/loft spaces) above. The construction should include any slabs, insulation and suspended ceiling layers. DesignBuilder determines which of the zones is relatively 'exterior' and uses this information to correctly order the material layers in the roof. If there are no semi-exposed ceiling surfaces, just ignore this data.

Note: the semi-exposed ceiling data is defined from the occupied zone side only. If you navigate to the other side of the surface (the semi-exterior unconditioned zone floor) the data is not available for access.

Semi-exposed floor

The semi-exposed floor construction is used between occupied zones and [Semi-exterior unconditioned spaces](#) below. The construction should include any slabs, insulation and raised floor layers. If there are no semi-exposed floor surfaces, just ignore this data.

Note: This data is accessed from the occupied zone side only and cannot be accessed from the ceiling surface of the semi-exterior unconditioned zone below.

External door

Select the construction to be used to represent external doors.

Note: Doors use opaque constructions and so if the door you wish to model is transparent then it should be modelled using a window. If only a portion of the door is glazed then the door could be modelled as part door and part window.

Internal door

Select the construction to be used to represent internal doors.

Note: this data is not available at zone level to avoid ambiguity when different settings are made in adjacent zones. Surface level internal door settings are generally inherited from block level, however settings for *inter-block* internal doors are inherited from the building level. For details on these rules see: "Zone Level Data for Internal Surfaces" on page 700.

Floors

Ground floor

The ground floor construction is used between internal zones and the ground. The [site ground temperatures](#) are applied to the outside of all surfaces adjacent to ground. If there are no ground-adjacent floor or wall surfaces this data can be ignored.

Note: Constructions of type **6-F-Factor** can be selected here for both ASHRAE 90.1 and non-ASHRAE 90.1 models, however for surfaces with zero exposed perimeter the behaviour depends on whether it is an ASHRAE 90.1 model. For ASHRAE 90.1 models the **Basement ground floor** construction (below) is used instead. For non-ASHRAE 90.1 models an error message will be generated.

Basement ground floor

Used for ASHRAE 90.1 models only, the **Basement ground floor** construction is applied to ground adjacent floors whose zone has no external perimeter, which normally means it is a basement. The [site ground temperatures](#) are applied to the outside of these basement ground floor surfaces. If there are no basement ground floor surfaces in the model, this data can be ignored.

Note: The Basement ground floor is provided to help distinguish slab-on-grade floors from other floors. It is normally outside the scope of slab-on-grade floor definition described in ASHRAE 90.1 and is not regulated by the 90.1 Standard. In DesignBuilder, the baseline model uses the same construction for Basement ground floor as that used in the proposed model, typically a standard layered floor construction (as opposed to an F-Factor construction normally used for slab on grade floors).

External floor

External floors are floors that are adjacent to outside air, e.g. the floor of a cantilevered part of the building or where for any other reason there is no ground or other zone below. The External floor construction should include any slabs, insulation and raised floor layers. If there are no external floor surfaces, just ignore this data.

Internal floor

The internal floor construction defines the makeup of floors between occupied zones including any slabs, air gaps, raised floors and suspended ceilings. It will not usually contain insulation. Where the zone above is unoccupied the **semi-exposed ceiling** construction is used instead. Likewise where the zone below is unoccupied the **Semi-exposed floor** construction is used instead. If there are no internal floor surfaces, just ignore this data.

Navigator Use - Surface Level

When working with constructions it is often useful to view and make settings at surface level as this is the data that is actually used in calculations. Building, block and zone construction data is used as defaults for surface level data.

On the Navigator panel, for each surface, you will see one or more adjacency items listed below and to the right as shown in the highlighted region of the screenshot below. Clicking on any of the highlighted items in the navigator list will take you to the same surface level.

Important Note: DesignBuilder does not provide direct access to adjacency level data in the editor. For example, in the above screenshot, when navigating to the surface level by clicking on the "External/internal floor - 131.061 m2" item you will be working at the same surface level and with the same data as if you had navigated to one of the adjacency items below, e.g. "External floor element - 31.061 m2". You can set the construction type of both the external and internal floors from the surface level.

Zone Statistics

Zone Volume

The zone volume is calculated for all zone geometries and by default, the volume is the actual air volume of the space excluding the volume of floor and ceiling constructions but including half the volume of partition walls. The volume of the floor constructions can be optionally subtracted from the zone volume by using the [Zone volume calculation](#) Model options.

Other related information

1. [Block and Zone Dimensions](#) is an introductory section explaining how to enter blocks and the relationship with zones.
2. Also see [Constructions](#) for how to edit the construction configuration.
3. And the Model Geometry Example section for a detailed worked example illustrating how surface areas and volumes are calculated.

Sub-Surface Constructions

[Construction tab](#) in model data under [Construction header](#)

Sub-surfaces are used to define areas of a surface having a different construction to that of the main surface construction. Typical examples include cold-bridging elements such as window lintels and opaque panels in a lightweight façade. You can define different sub-surface construction types for external walls, internal partitions and pitched roofs. This makes it easier to set up defaults at building, block, zone or surface level.

Sub-surfaces are modelled to the same level of detail as standard surfaces including the effect of thermal mass but not including any 2-D or 3-D heat conduction effects due to the interface between the sub-surface and the background parent surface.

To **add** a sub-surface, go to the surface you wish to work on, click on the Layout tab and select the [Draw sub-surface](#) command.

You can also define default constructions for doors under the Sub-Surfaces header.

Sub-Surfaces	
 Walls	Project wall sub-surface construction
 Internal	Project internal wall sub-surface construction
 Roof	Project roof sub-surface construction
 External door	Project external door
 Internal door	Project internal door

The sub-surface constructions defined here are applied to sub-surfaces placed on the various base surface types as follows.

Walls

Any [sub-surfaces](#) created in a wall or ground floor will have this construction.

Internal

Any [sub-surfaces](#) created in any inside surface (partitions, internal floor etc) will have this construction.

Note: You can set Internal sub-surface defaults at building, block and surface levels. The Internal sub-surface option is not available at zone level to avoid possible ambiguity with sub-surfaces placed on internal walls between 2 different zones which could otherwise potentially have different settings.

Roof

Any [sub-surfaces](#) created in any pitched or flat roof will have this construction.

External door

Defines the construction of external doors.

Internal door

Defines the construction of internal doors.

Note: You can set Internal door defaults at building, block and surface levels. The Internal door option is not available at zone level to avoid possible ambiguity with doors placed on internal walls between 2 different zones which could otherwise potentially have different settings.

Internal Thermal Mass

[Construction tab](#) in model data under [Construction header](#)

DesignBuilder uses the thermal characteristics of the constructions for each of the walls, floors, roofs, partitions etc in each zone and accounts for the thermal mass in the simulations. You can also include additional thermal mass to account for partitions within a zone, furniture and any other mass which will affect the dynamic thermal response of the zone. There are two ways you can define additional internal thermal mass in DesignBuilder:

1. Drawing [hanging partitions](#) (i.e. partitions which do not meet other walls at both ends),
2. Entering a non-zero internal thermal mass exposed area on the Constructions tab under the [Internal Thermal Mass](#) header at zone level.

Construction

Thermal mass defined using these methods is lumped together for each zone and modelled in EnergyPlus in a 'non-geometric' way. In both cases, the associated construction is defined under the [Internal Thermal Mass](#) header on the Constructions tab.

Internal thermal mass defined in this way is used to specify the construction and area of items within the space that are important to heat transfer calculations but not necessarily important geometrically. For example, furniture within the space – particularly for large spaces. It can also be used for internal walls that are not needed for solar distribution, when [Solar distribution](#) is set to **3-Full interior and exterior** or to represent all interior walls when solar is distributed to the floors only with [Solar distribution](#) set to **2-Full exterior**.

Example

When zoning an office building, five west-facing offices have been combined into one zone. All of the offices have interior walls made of the same materials. As shown in the figure below, this zone may be described with 5 exterior walls and 11 internal walls or 1 exterior wall and 1 internal mass. Note that fewer surfaces will speed up the EnergyPlus calculations.

Example

A five-story building has the same ceiling/floor construction separating each of the levels. Zones that are on floors 2 through 4 may be described using a single piece of internal mass to represent both the floor and ceiling. The construction for this internal mass would be identical to the ceiling/floor construction that would be used to describe separate surfaces.

Exposed Area

The exposed area is the surface area of the internal mass. The area that is specified must be the entire surface area that is exposed to the zone. If both sides of a wall are completely within the same zone, then the area of both sides must be included when describing that internal wall.

Zone capacitance multiplier (Research Option)

This data can be used at building level only to control the effective storage capacity of the air in all zones in the building. Capacitance multipliers of 1.0 indicate the capacitance is that of the (moist) air in the volume of the specified zone. This multiplier can be increased if the zone air capacitance needs to be increased for stability of the simulation or to allow modelling higher or lower levels of damping of behaviour over time. The multipliers are applied to the base value corresponding to the total capacitance for the zone's volume of air at current zone (moist) conditions.

Typical values will be in the range 1 to 20.

Tip: The Zone capacitance multiplier can also be used to model the increase of air capacity due to lightweight thermal mass which could be considered to be mixed with the air. Examples include furniture, papers and any other items which might increase the effective thermal mass of the building zone response. For example, work at LBNL (Leveraging Zone Air Temperature Data to Improve Physics-Based Energy Simulation of Existing Buildings, by Sang Hoon Lee, Tianzhen Hong) suggests:

"The internal mass validation study using the DOE reference energy models (Deru et al. 2011) shows that a multiplier of 8.0 reflects a typical office configuration. An internal mass multiplier of 3 to 6 is recommended for light offices, 6 to 10 for typical offices, and 10 to 15 for heavy mass office configurations."

Adjacency

Construction tab in model data under Construction header

The adjacency of individual surfaces can be set to be either adjacent to ground or adiabatic.

The available options are:

- **1-Auto** - the adjacency of the surface is determined automatically by DesignBuilder based on its position. This is the default setting where external surfaces below the ground plane are considered to be adjacent to ground and external surfaces above the ground plane are considered to be adjacent to outside conditions.
- **2-Not adjacent to ground** - the surface is not adjacent to ground even if it is situated on or below the ground plane.
- **3-Adjacent to ground** - the surface is adjacent to ground even if it is above the ground plane or it is an internal surface.
- **4-Adiabatic** - the surface is adiabatic. This means that heat is not transferred across in its external surface. Adiabatic surfaces are frequently used in thermal modelling to represent surfaces which are between two zones at similar conditions. Note that thermal mass is still modelled in Adiabatic surfaces because heat can still be transferred into the mass through the internal surface. Adiabatic surfaces are often used for modelling the boundary between the actual building model and any [adjacent buildings](#) which are not to be modelled.

You can determine which surfaces are adiabatic or adjacent to ground by looking for the corresponding surface adjacency markers in the Edit Screen at zone and surface levels:

Adiabatic

Adjacent to ground

Tip: The recommended way to set ground and adiabatic adjacencies is to use ground or adiabatic [component blocks](#). Or, if for any reason that isn't practical and you need to set multiple surface adjacencies you can use the [Model data grid view](#).

Adiabatic surfaces

Adiabatic surfaces are modelled as being adjacent to the same conditions as the current zone and always use internal constructions:

- Adiabatic external floors use [Internal floor construction](#).
- Adiabatic flat roofs use the *reversed* [Internal floor construction](#).
- Adiabatic external wall surfaces use the [Internal partition construction](#).

Note: All openings and sub-surfaces in adiabatic surfaces are ignored in EnergyPlus simulations

Exclude this surface area from total zone floor area?

When modelling situations such as offices space within large warehouse zones where the ceiling at the top of the offices is not usable floor area in the warehouse it may be useful to exclude the area of any unused floor surfaces from the floor area of the zone above. An example of this situation is shown on the [Warehouse with Office](#) page.

For internal floors such as the unused 'floor' on top of the office space you can check the surface level **Exclude this surface area from total zone floor area?** checkbox to ensure the floor is not used in the calculation of zone and building floor area and in the calculation of internal gains where defined per m2 or per ft2.

Note this surface setting should *not* be made for the floor of office zone itself, which of course is usable floor area, but for the 'floor' of the zone above (typically a warehouse or other large volume space) which is not usable floor area.

Another situation where this option can be used is where holes have been cut in a floor surface to remove it, so upper and lower zones can be [merged](#). In this case, any small remaining border in the cut floor surface should ideally be removed from the floor area calculation for the combined zone.

Geometry Areas And Volumes

DesignBuilder provides a great deal of flexibility in the way that block and zone geometry is defined and passed through to the various calculations. There are various options including building blocks drawn using external measurements while providing correct internal zone geometry for floor area and zone volume calculations derived from actual surface thickness. It is also possible to use a simpler approach where the block and zone dimensions drawn are exactly the ones used in calculations and the thickness of the surfaces are not considered in the analysis.

Geometry convention template

Select the template which best fits the way you would like to define the building geometry. Templates provided include:

- **Simple** - where the zone surfaces, floor areas and volumes used in calculations are all derived directly from the drawn block and zone dimensions. If blocks are drawn using internal measurements then the model would be considered to be using an internal convention and if blocks are drawn using outer dimensions then the model would be using the external convention. Likewise to obtain a centre-line convention simply draw blocks to the centre-line between inner and outer dimensions. This is the only option provided in most other energy simulation tools.
- **External measurements** - the default option for simulation where blocks are drawn using outer dimensions and the surfaces used in thermal calculations are derived from the zone outer geometry and air volumes and floor areas are derived from the zone inner geometry. Note that this option works well for EnergyPlus simulations but is not compatible with the UK NCM which requires internal surface dimensions to be used in heat transfer calculations.
- **External measurements to top of roof** - like **External measurements** but zone geometry extends to the top of flat roofs.
- **DesignBuilder pre-v4 compatibility** - surfaces are derived in the same way as in v3 and earlier where a single "Block wall thickness" setting was used to define the thickness of all external wall surfaces in the block. For v3 and earlier models loaded to v4 and later the old "Block wall thickness" attribute is used to set the [External wall thickness](#) at block level.
- **External measurements, internal zone geometry** - blocks are defined using external measurements and surfaces dimensions, zone volume and floors areas are all derived from the inner zone geometry.
- **UK NCM external perimeter** - blocks are drawn using external measurements and simulations use internal measurements for surfaces, floor area and zone volume. The thickness of external wall and pitched roof constructions is used to define the inner zone surfaces, volume etc. Use this template for NCM work where the model has been or is to be defined using external block measurements. It may be useful in cases where a model previously drawn using external measurements is to be used or when importing from BIM where surfaces represent the external building geometry.

- **UK NCM internal perimeter** - blocks are drawn using internal measurements and simulations use those internal measurements for surfaces, floor area and zone volume. Use this template for NCM work as the easiest option on projects where it is possible to draw or import internal building geometry.

The usual inheritance mechanism applies so loading the required template at building level defines the geometry convention for the whole building. Settings can be made at building level only but [Fixed surface thicknesses](#) can be defined down to surface level and [Void depths](#) can be defined down to Zone level.

The Geometry convention template can also selected when creating a [new building](#).

Tip: After making any changes to the model which could affect the geometry including construction type selection as well as the settings described on this page, you should manually refresh the Navigator by

pressing the Refresh  Navigator toolbar icon. This will ensure that the Navigator is synchronised with the model.

Zone geometry and surface areas

This setting defines whether the geometric surface data used in the calculation (heat transfer etc) is based on the inner or outer zone volume dimensions. Options are:

- **1-Inner** - where the surface dimensions and areas used in thermal calculations are derived from the zone inner geometry. This is obtained from the outer zone geometry and "deflated" by the thickness of each surface and any floor or ceiling voids. For each type of surface the thickness comes from either a) the construction thickness or b) an overriding value set under [Fixed Surface Thickness](#) header. **You should carefully check the notes below when using this option.**
- **2-Outer** - where the surface dimensions and areas used in thermal calculations are derived from the zone outer geometry, which for a single zone block is exactly equal to the block outer dimensions.

Note 1: In cases where the **1-Inner volume** option is selected and non-zero surface thickness settings are being used, any component block shading devices placed adjacent to the block at building level will not be exactly adjacent to the corresponding zone inner surfaces used in the simulations which are offset inwards from the block outer geometry. The resultant gap will allow solar radiation to pass into the windows which will not be apparent by looking at the model at building level or on the visualisation screen. You are therefore advised to avoid using the combination of **1-Inner volume** geometry, non-zero surface thickness and external component blocks used as local shading devices. This issue does not arise with the [local shading](#) mechanism which ensures that overhangs, sidefins and louvre blades are offset with the window.

Note 2: In cases where the **1-Inner volume** option is selected and non-zero surface thickness settings are being used, for some zone geometries, the inner volume cannot be generated and in this case the zone outer surfaces will be used instead. This issue is discussed in more detail below under [Special Conditions](#).

Zone volume calculation method

This setting dictates whether internal or external measurements are used to calculate the zone volume is required to calculate air volumes etc.

- **1-Inner** - where the zone volume used in thermal calculations is derived from the zone inner geometry.
- **2-Outer** - where the zone volume used in thermal calculations is derived from the zone outer geometry.

Note: Unless otherwise specified by your regional modelling code, the **1-Inner volume** setting should generally be used for calculating zone volume to allow it to account for the effects of surface thickness and any floor and ceiling voids included.

Zone floor area calculation method

This setting dictates whether internal or external measurements are used to calculate the zone floor area. The options are:

- **1-Inner** - where the zone volume used in thermal calculations is derived from the zone inner geometry.
- **2-Outer** - where the zone volume used in thermal calculations is derived from the zone outer geometry.

The floor area calculated from the method selected here is used for:

- The Zone floor area used for calculating occupancy and other internal gains from the user-defined per floor area values.
- Occupied and Unoccupied "Floor Areas and Volumes" on page 333 reported at building level on the Activity tab.
- Floor area values for general reporting, e.g. in UK Part-L and EPC reports.

Note: Unless otherwise specified by your regional modelling code, the **1-Inner volume** setting should generally be used for calculating zone floor area.

Tip: For zones with walls that have a finite thickness, this floor area will not be the same as the total area of the floor surfaces listed in the Navigator, whose geometry is based on the [Zone geometry and surface areas](#) method.

Window to wall ratio method

This setting is used to specify whether or not the outside wall surface or inside wall surface is to be used to calculate the available area for glazing. This option is only visible when the [Zone geometry and surface areas](#) option is set to **2-Outer**. Options are:

- **1-Inner**, where the glazing layout for default (non-custom) façades are calculated based on the available internal area of external walls. For example if there is a non-zero height ceiling void (using the [Ceiling void depth](#) attribute) then the wall area seen from inside will be less than the area seen from outside, and this lower inside area is used in the calculation of the window size. Consider a case where the WWR is set to 100%. In this case the occupants inside the building will see external walls as being fully glazed, but people viewing from outside will see the areas of the outside wall where the ceiling voids are as opaque. Another example of how this setting affects façade layouts is that the sill height of default glazing is defined with reference to the top of the internal floor not the base of the block. Note that custom openings are unaffected by this setting.
- **2-Outer**, where the whole of the outer wall surface is used in calculating the window sizes. When this option is set and a 100% WWR is specified people viewing from outside will see a fully glazed building. In general it is more obvious how this setting works since there is only one wall area to consider.

Important Note: When the **Window to wall ratio method** is set to use the **2-Outer** wall surface, rendered views on the Visualisation, Daylighting and CFD screens will default to a single skin display. Therefore all surface elements including walls, partitions, floors, ceilings and roofs are displayed without thickness, and floor and ceiling voids are not displayed. This allows full size windows to be rendered accurately. Special treatment is required for this option because windows can occupy the whole surface and in that case it wouldn't be possible to show the extent of the windows together with the element thicknesses.

Also, because daylighting calculations use the same elements as seen on the Visualisation screen, the results will be based on the geometry seen there. So depending on the geometry of your model, the **2-Outer** option may not be ideal if you are planning to use the model to run daylighting calculations.

Fixed Surface Thicknesses

Each surface can have its geometric thickness calculated from the construction selected but only when the checkbox for the associated surface type (list below) is unchecked. If the thickness is to be overridden then check the appropriate checkbox and enter the fixed surface thickness. Settings can be made from building level right down to surface level giving considerable flexibility over the model geometry.

In most cases you should simply select the [Geometry convention template](#) - you shouldn't normally need to override the surface thickness settings below.

When at zone level, the fixed surface thickness for internal surfaces are not displayed due to the ambiguity involved if the 2 zones involved in the connecting internal surface have different settings. This applies to Internal partitions, Internal floor, Semi-exposed wall, Semi-exposed floor and Semi-exposed ceiling data.

Note: The surface thickness does not affect the thermal properties of the wall/floor/roof etc (U-value, thermal mass etc). Surface thermal properties are based purely on the construction data specified for the surface.

External wall

If the external wall surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the wall thickness (in m or in).

Below grade wall

If the below grade wall surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the wall thickness (in m or in).

Internal partition

If the partition surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the wall thickness (in m or in).

Ground floor

If the ground floor surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the floor thickness (in m or in).

Note: In most cases ground floor blocks are measured from ground level and the ground slab construction is not included in the volume of the building so this setting is normally overridden to be zero.

Basement ground floor

The basement ground floor is the construction used for underground ground floors (i.e. the floor is located at a height lower than $z=0$). If the basement ground floor surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the floor thickness (in m or in).

External floor

If the external floor surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the floor thickness (in m or in).

Internal floor

If the internal floor surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the floor thickness (in m or in).

Semi-exposed wall

If the semi-exposed wall surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the wall thickness (in m or in).

Semi-exposed floor

If the semi-exposed floor surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the floor thickness (in m or in).

Semi-exposed ceiling

If the semi-exposed ceiling surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the ceiling thickness (in m or in).

Flat roof

If the flat roof surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the flat roof thickness (in m or in).

Pitched roof

If the pitched roof surface thickness is to be overridden (i.e. not derived from construction thickness) then check the checkbox and enter the pitched roof thickness (in m or in).

Considerations For CFD

DesignBuilder [CFD](#) can include multiple zones in a single domain, but in this case it is important to ensure that all internal partitions and floors/ceilings separating zones in the domain have finite (non-zero) thickness. Any internal surfaces in the domain with zero thickness will be ignored in the analysis and so will not present a barrier to air flow.

Considerations For Parametric Analysis And Optimisation

When running parametric or optimisation studies in which wall or other surface thickness are changed as part of the parametric variations, there can be other significant knock-on impacts on the model geometry including varying floor area (and so internal gains, ventilation etc) and zone volume (and so ventilation and infiltration changes). To avoid running into these issues you can fix surface thickness for the relevant part of the model. For example if wall insulation thickness is being varied in a parametric analysis and you don't wish these changes to impact on zone floor area and volume then you could apply a constant External wall thickness.

Tip: the easiest way to avoid any such issues would be to use the "Simple" Geometry conventions template at the outset.

Void Depths

Ceiling void depth

The depth of the ceiling void (in m or in). This is used, in addition to any surface thickness applied to the ceiling/roof surface to reduce the size of the zone inner volume and surfaces areas to account for the ceiling void.

When using the [1-Inner](#) Zone geometry and surface areas option, ceiling voids will reduce the height of zone wall surfaces used in the simulation. Also when using the [1-Inner](#) Zone volume calculation method option, ceiling voids will reduce the zone volume for air flow and heat exchange calculations.

Note: If the ceiling/roof construction already includes an air gap to define the ceiling void and its thickness is being used to define the inner volume then you should enter 0 here. Likewise, if the ceiling void is already modelled using its own zone then enter 0.

Floor void depth

The depth of the floor void (in m or in). This is used, in addition to any surface thickness applied to the floor surface to reduce the size of the zone inner volume and surfaces areas to account for the floor void.

When using the **1-Inner** Zone geometry and surface areas option, floor voids will reduce the height of the zone wall surfaces used in the simulation. Also when using the **1-Inner** Zone volume calculation method option, floor voids will reduce the zone volume for air flow and heat exchange calculations.

Note: If the floor construction already includes an air gap for the floor void and its thickness is being used to define the inner volume then you should enter 0 here. Likewise, if the floor void is already modelled using its own zone then enter 0.

Technical: EnergyPlus Zone Floor Area and Volume Checking

When writing out zone floor area and volume settings to the EnergyPlus input data, DesignBuilder uses the geometry convention settings described above. This ensures that the real usable floor area and actual zone air volume are used in the simulation. In many cases these values will be less than the values that EnergyPlus estimates when carrying out its input checking which is based only on the 2-D surfaces that make up the zone geometry. You will therefore often see warnings generated in the error file such as:

```
** Warning ** Entered Zone Volumes differ from calculated zone volume(s).
** ~~~ ** ...use Output:Diagnostics,DisplayExtraWarnings; to show more details on individual zones.
```

You can safely ignore these warnings.

Special Conditions

Inner geometry cannot be generated

When using **1-Inner Zone geometry and surface areas** option, DesignBuilder creates an "inner volume" by moving all zone surfaces inwards using the construction thicknesses (or fixed thicknesses where specified). This process is called "deflation". In some cases, however the deflation process is not possible and the inner volume cannot be generated. The two main reasons for this failure are:

1. When the resulting inner volume geometry will not physically fit, often due to the surface thickness being too great. Examples of this situation include small kinks in the surface geometry with dimension of 2 x the surface thickness or less (image below) and zones where there are acute angle corners and thick wall constructions.

If dimension A is less than 2 x the wall thickness (however that is calculated) then the zone inner volume cannot be calculated

2. Zones where one or more zone outer geometry vertex has 4 or more surfaces adjacent.

If the deflation process fails, the software uses an alternative mechanism in which the zone *outer* geometry is used for all zone thermal surfaces. Although DesignBuilder is unable to generate full inner zone geometry for these zones it can still calculate zone inner volumes and floor areas fairly accurately using a simpler algorithm based on the outer zone geometry and surface thicknesses.

Zone inner geometry is calculated zone by zone and so if the deflation process fails for 1 zone in a block, this should not affect the process in other zones in the block.

Wall thickness is weighted average

In cases where a surface is made up of more than one adjacency, each using a different construction, DesignBuilder must use an area-weighted average surface thickness. For example:

- When a wall surface has two different thickness, e.g. internal and external. This case is illustrated below.
- When the ceiling surface has two different thickness (flat roof and internal floor).

Geometry Convention Examples

External measurements, perspective view

External measurements, section view

Curtain Glazing - Example

When modelling continuous glazing for curtain walls, atria, greenhouses etc. it is often necessary to model glazing joining at the corners. It is not possible for windows to literally meet in this way because EnergyPlus requires all openings (windows, doors etc) to be placed on a parent surface with at least a small gap between the opening and the parent surface edge. But by using a low value of wall surface thickness you can give the appearance of adjacent windows as shown below.

A small wall thickness, below, allows the glazing to cover most of the wall giving good results (below).

A larger wall thickness, below, requires more area to cater for the walls joining at the corners and the glazing does not meet 'round the corner' giving poor results (below).

Surface Convection

[Construction tab](#) in model data under [Construction header](#)

You can select the inside and outside surface convection algorithms in the Model data on the Construction tab under the Surface Convection header. This allows you to make different selections in different parts of the building. Further details of the algorithms are provided in the [EnergyPlus Engineering reference document](#).

Tip: You can override the inside and outside convection algorithm selection described below by setting fixed values on the [Surface tab of the Construction component dialog](#).

Inside convection algorithm

You can select from 6 main EnergyPlus inside convection algorithms for calculating the convection between internal zone surfaces and the rest of the zone air in the simulation calculations. Unless you have good reason to do so you are advised to use the default TARP convection algorithm:

- **1-AdaptiveConvectionAlgorithm** -This advanced option provides a dynamic selection of convection models based on conditions. Beausoleil-Morrison (2000, 2002) developed a methodology for dynamically managing the selection of h_c equations called adaptive convection algorithm. The algorithm is used to select among the available h_c equations for the one that is most appropriate for a given surface at a given time. As Beausoleil-Morrison notes, the adaptive convection algorithm is intended to be expanded and altered to reflect different classification schemes and/or new h_c equations. The adaptive convection algorithm implemented in EnergyPlus for the inside face has a total of 45 different

categories for surfaces and 29 different options for h_c equation selections. The tables provided in the Engineering document summarise the categories and the default assignments for h_c equations.

- **2-Simple** - The simple convection model uses constant coefficients for different heat transfer configurations, using the criteria to determine reduced and enhanced convection. The coefficients are taken directly from Walton (1983). Walton derived his coefficients from the surface conductances for $\epsilon=0.90$ found in the ASHRAE Handbook (1985) in Table 1 on p. 23.2. The radiative heat transfer component was estimated at $1.02 \times 0.9 = 0.918$ BTU/h-ft²-F and then subtracted off. Finally the coefficients were converted to SI units to yield the values below. For a vertical surface: $h_c = 3.076$ For a horizontal surface with reduced convection: $h_c = 0.948$ For a horizontal surface with enhanced convection: $h_c = 4.040$ For a tilted surface with reduced convection: $h_c = 2.281$ For a tilted surface with enhanced convection: $h_c = 3.870$.
- **3-CIBSE** - applies constant heat transfer coefficient derived from traditional CIBSE values.
- **4-Ceiling diffuser** - a mixed and forced convection model for ceiling diffuser configurations. The model correlates the heat transfer coefficient to the air change rate for ceilings, walls and floors. The ceiling diffuser algorithm is based on empirical correlations developed by Fisher and Pedersen (1997). The correlation was reformulated to use the room outlet temperature as the reference temperature. The correlations are shown below. For Floors: $h_c = 3.873 + 0.082 \times \text{ACH}^{0.98}$, For ceilings: $h_c = 2.234 + 4.099 \times \text{ACH}^{0.503}$ and for Walls: $h_c = 1.208 + 1.012 \times \text{ACH}^{0.604}$.
- **5-Cavity** - This algorithm was developed to model convection in a "Trombe wall zone", i.e. the air space between the storage wall surface and the exterior glazing. (See the later sections on Passive and Active Trombe Walls below for more information about Trombe walls.) The algorithm is identical to the convection model (based on ISO 15099) used in Window5 for convection between glazing layers in multi-pane window systems. The use of the algorithm for modelling an unvented Trombe wall has been validated against experimental data by Ellis (2003). This algorithm gives the convection coefficients for air in a narrow vertical cavity that is sealed and not ventilated. This applies both to the air gap in between panes of a window or to the air gap between the Trombe wall glazing and the inner surface (often a selective surface). These convection coefficients are really the only difference between a normal zone and a Trombe zone. See also note below.
- **6-TARP** - based on variable natural convection based on temperature difference from ASHRAE algorithms. This is the same as the old "Detailed" Inside convection algorithm provided in earlier versions of DesignBuilder. ***It is the default option for new models in v3.0.0.085 and later.***

The **5-Cavity** Inside convection algorithm is not available at the surface level.

Paraphrased note from EnergyPlus developers on the 5-Cavity option: "The Trombe wall convection coefficients only make sense for a zone. They are specific coefficients calculated for a narrow enclosed space. The two major walls of a Trombe wall zone are so close together that the convection patterns for the two walls actually interact. If they are close enough they can fight each other and totally stagnate the convection cell in the space. This is not free-boundary convection such as that found in a typical room. Therefore, it does not make sense to apply these coefficients to a single surface. The algorithm analyses the zone to figure out which are the two major surfaces and then sets the coefficients on those surfaces. The other minor surfaces receive negligible convection."

The following inside convection options are also available for advanced users:

- 7-ASHRAEVerticalWall
- 8-WaltonUnstableHorizontalOrTilt
- 9-WaltonStableHorizontalOrTilt
- 10-FisherPedersenCeilingDiffuserWalls
- 11-FisherPedersenCeilingDiffuserCeiling
- 12-FisherPedersenCeilingDiffuserFloor
- 13-AlamdariHammondStableHorizontal
- 14-AlamdariHammondUnstableHorizontal
- 15-AlamdariHammondVerticalWall
- 16-KhalifaEq3WallAwayFromHeat
- 17-KhalifaEq4CeilingAwayFromHeat
- 18-KhalifaEq5WallNearHeat
- 19-KhalifaEq6NonHeatedWalls
- 20-KhalifaEq7Ceiling
- 21-AwbiHattonHeatedFloor

- 22-AwbiHattonHeatedWall
- 23-BeausoleilMorrisonMixedAssistedWall
- 24-BeausoleilMorrisonMixedOpposingWall
- 25-BeausoleilMorrisonMixedStableFloor
- 26-BeausoleilMorrisonMixedUnstableFloor
- 27-BeausoleilMorrisonMixedStableCeiling
- 28-BeausoleilMorrisonMixedUnstableCeiling
- 29-FohannoPolidoriVerticalWall
- 30-KaradagChilledCeiling
- 31-ISO15099Windows
- 32-GoldsteinNovoselacCeilingDiffuserWindow
- 33-GoldsteinNovoselacCeilingDiffuserWalls
- 34-GoldsteinNovoselacCeilingDiffuserFloor

To avoid discontinuities in surface heat transfer rate calculations, all correlations are extrapolated beyond the lower limit of the data set (3 ACH) to a natural convection limit which is applied during the hours when the system is off. These models are explained in greater detail in the EnergyPlus Engineering Reference Document.

Outside convection algorithm

Substantial research has gone into the formulation of models for estimating the exterior convection coefficient. Since the 1930's there have been many different methods published for calculating this coefficient, with much disparity between them (Cole and Sturrock 1977; Yazdanian and Klems 1994). Unless you have good reason to do so you are advised to use the default DOE-2 convection algorithm. You can select from 7 main outside convection algorithms:

- **1-AdaptiveConvectionAlgorithm** - This advanced convection algorithm provides a dynamic selection of convection models based on conditions. This algorithm has a structure that allows for finer control over the models used for particular surfaces. The algorithm for the outside face was developed for EnergyPlus but it borrows concepts and its name from the research done by Beausoleil-Morrison (2000, 2002) for convection at the inside face (see [above](#)). The adaptive convection algorithm implemented in EnergyPlus for the outside face is much simpler than that for the inside face. The surface classification system has a total of 4 different categories for surfaces that depend on current wind direction and heat flow directions. However in other ways it is more complex in that the equation is split into two parts and there are separate model equation selections for forced and natural convection.
- **2-SimpleCombined** - The simple algorithm uses surface roughness and local surface wind speed to calculate the exterior heat transfer coefficient. This is a combined heat transfer coefficient that *includes radiation to sky, ground, and air*. The correlation is based on Figure 1, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals.

Note: selecting the **SimpleCombined** option at *building level* on the Constructions tab under [Surface Convection](#) or on the Calculation options or Model options dialogs has a special meaning. In this case the outside convective selection covers both convection and radiation combined. This means for example that any hard-set outside convective heat transfer coefficients set on the [Surface properties](#) tab of the Construction dialog will actually be used as a *combined* outside convective plus radiation coefficient.

- **3-CIBSE** - applies constant heat transfer coefficients depending on orientation, derived from traditional CIBSE values.
- **4-ASHRAEVerticalWall** - Identical to the DOE-2 option.
- **5-TARP** - TARP, or Thermal Analysis Research Program, is an important predecessor of EnergyPlus (Walton 1983). Walton developed a comprehensive model for exterior convection by blending correlations from ASHRAE and flat plate experiments by Sparrow et. al. In older versions of EnergyPlus, prior to version 6, the "TARP" model was called "Detailed." The model was re-implemented in version 6 to use Area and Perimeter values for the group of surfaces that make up a facade or roof, rather than the single surface being modelled.
- **6-DOE-2** - The DOE-2 convection model is a combination of the MoWiTT and BLAST Detailed convection models (LBL 1994). ***It is the default option for new models.***

- **7-MoWiTT** - The MoWiTT model is based on measurements taken at the Mobile Window Thermal Test (MoWiTT) facility (Yazdanian and Klems 1994). The correlation applies to very smooth, vertical surfaces (e.g. window glass) in low-rise buildings. The MoWiTT algorithm may not be appropriate for rough surfaces, high-rise surfaces, or surfaces that employ movable insulation.

The following outside convection options are also available for more advanced users:

- 8-WaltonUnstableHorizontalOrTilt
- 9-WaltonStableHorizontalOrTilt
- 10-AlamdariHammondStableHorizontal
- 11-AlamdariHammondUnstableHorizontal
- 12-FohannoPolidoriVerticalWall
- 13-NusseltJurges
- 14-McAdams
- 15-Mitchell
- 16-BlockenWindard
- 17-Emmel
- 18-ClearRoof

Note: When the surface is wet (i.e. it is raining and the surface is exposed to wind) then the convection coefficient appears in results as a very large number (1000) and the surface is exposed to the Outdoor Wet Bulb Temperature rather than the Outdoor Dry Bulb Temperature.

As well as being able to define convection options on the Model data on Construction tab under the [Surface Convection](#) header as described above, building level inside and outside convection algorithm settings can be made on:

- Model options dialog ([Heating design](#), [Cooling design](#), [Simulation](#) tabs)
- Calculation options dialogs ([Heating design](#), [Cooling design](#), [Simulation](#))

You cannot make changes to individual surface convection settings where the surface is an internal partition.

All of the above algorithms are described fully in the [EnergyPlus Engineering Reference](#).

Note: the equivalent inside and outside surface convection options in the Calculation and Model options dialogs control **building default values** (equivalent of making a setting in Model data at building level) and any changes made at block, zone or surface levels in the Model data will override these default settings.

Component Block

[Construction tab](#) in model data under [Construction header](#)

[Component blocks](#) can be used to include shading and reflection effects of objects such as local shading devices, awnings, adjacent buildings and trees. They can also be used to define ground and adiabatic adjacencies. The component block model data allows you to define the component block type, whether the component block shades and reflects in simulations, transmittance of the shading material and also a schedule for modelling variations in transmittance at different times of the day, seasons etc. For example they can be used for modelling deciduous trees which shade more in the summer when they have leaves than they do in winter when the leaves have fallen.

Component block type

You can change the type of the component block. Select from:

- [1-Standard](#) - used for shading, reflection and visualisation.
- [2-Ground](#) - used for setting ground adjacency, shading, reflection and visualisation.

- **3-Adiabatic** - used for setting adiabatic adjacency, shading, reflection and visualisation.

For more information on the Component block types see [Component Block](#) under [Working with Blocks \(Building Level\)](#)

Shades and reflects

Switch this option on to include the component block as a shading/reflection surfaces in the simulations, or to include the component block in an LCA or cost analysis.

Shading surfaces have the following effects in an EnergyPlus simulation:

- Shade direct beam solar radiation.
- Reflect solar radiation onto the building (if you select [Model all external reflections and shading of ground reflected solar](#) in the calculation options).
- Shade diffuse solar and long-wave radiation from the sky.
- Shade diffuse solar radiation from the ground (if you select [Model reflections](#) in the calculation options).

Note: Solar and light reflection from the ground is included even if the solar [Model reflections](#) option is not used, but if reflections are not calculated the ground plane is considered unobstructed, i.e., the shadowing of the ground by the building itself or by component blocks is ignored. Shadowing of the ground by component blocks is only taken into account if the [Model reflections](#) option is used. Conclusion: Switch **Model reflections** on for the most accurate shading calculations.

Note: all component block types cast shadows in the [visualisations](#).

Level

This setting allows you to associate component blocks with either the building or the site, depending on whether they are in some way part of the building or a fixed part of the site layout. Most of the time you won't need to change it, but for some simulations it can be important to attach component blocks to the site rather than the building. For example if you are trying to optimise a building's orientation using the parametric or optimisation tools, or using the ASHRAE 90.1 automated baseline or UK DSM tools, you should leave component blocks that represent building structures such as shades and canopies set to the default building level. However for component blocks that represent *fixed* site objects such as other buildings or site topography, you should set these to be site level objects to ensure that they are not rotated with the building as part of any parametric variations.

Select whether the component block is considered to be part of the building or the site, choosing from:

- **1-Building** - the default option where the component block is considered to be part of the building and so is rotated with the building as part of parametric and optimisation studies where the [Building orientation](#) is varied. Typically, any component blocks used to model building shading, or other building objects such as steps, should be given this assignment. Building Level component blocks are also used in LCA analyses.
- **2-Site** - the component block is considered to be part of the fixed wider site, perhaps representing an existing building or a tree and so is not rotated with the building as part of parametric and optimisation studies.

Note: It is especially important to make the correct setting here for UK DSM and ASHRAE 90.1 Appendix G PRM buildings because any **1-Building** level standard component blocks are removed from the auto-generated notional and reference/baseline buildings. This is done based on the assumption that they represent shading devices that must be excluded to be in keeping with code rules. If the component block is intended to represent another building or other site object make sure to use the **2-Site** setting.

Tip: Any component blocks that need to remain in contact with building including ground component blocks must use the **1-Building** option. This may not be obvious because you may consider the ground to be part

of the site, but the important point to remember is that ground component blocks are used to create ground adjacencies for the building surfaces and so they should be considered as part of the building.

Material

The component block material is used to define the [solar and visible reflectance](#) of the block surfaces in Cooling design calculations and Simulations using real weather data when the [model reflections](#) calculation option is selected. It is also used for [LCA calculations](#).

Important Note: Component blocks do not absorb or conduct heat in any way - their only effect on building surfaces in simulations is related to the shading and reflection of short-wave solar radiation and light. In cases where the component block touches the building, the material associated with the component block and the thickness of the block are not used in any way to modify the conduction of heat.

Note: Although component blocks are displayed in DesignBuilder as solid objects, non-flat component blocks are modelled in EnergyPlus as a group of surfaces and it is the reflectance and transmission of each of these surfaces that is being described here. The solar flux incident upon a building façade will be attenuated by each successive shading object located on a path between the façade and the sun position.

Flat surface position

If the component block is determined to be flat (based on the [Maximum flat surface thickness](#) threshold accessible on the Advanced tab of the Model options dialog, you can control how the single surface used to represent a flat component block in simulations is defined. Choose from:

- **1-Upper surface**, where the uppermost of the 2 largest component block surfaces is used.
- **2-Lower surface**, where the lowermost of the 2 largest component block surfaces is used.
- **3-Midway surface**, where a surface midway between the lowermost and uppermost large component block surfaces is used in simulations.
- **4-All surfaces**, where flat components are represented using all surfaces like non-flat component blocks.

Maximum Transmittance

Warning: For *flat, partially transmitting* component blocks you must ensure that the blocks are either rectangular or triangular in shape. More complex shaped *flat, partially transmitting* component blocks will not transmit solar radiation and light as expected.

Flat, partially transmitting component blocks must be rectangular or triangular in shape to ensure correct solar and light transmission.

This is the maximum solar transmittance of the entire component block to be used in EnergyPlus simulations. The transmittance of the component block during the simulation is calculated by multiplying the maximum transmittance by the time varying schedule value:

$$\text{Transmittance} = \text{Max Transmittance} \times \text{Schedule value}$$

You will generally want component blocks to provide 100% shading for 100% of the time. In this case you can leave the **Maximum transmittance** and **Transmittance schedule** in their default states of 0 and **On** respectively. If you wish the component block to transmit solar and visible radiation you can define the extent and timing of the transmission. The component block transmittance is calculated during the simulations as the **Maximum transmittance** multiplied by the value of the transmittance schedule below. The maximum transmittance can have any value between 0 and 1. Note that if the component block is [flat](#) (i.e. it consists of 2 large surfaces and several smaller 'edge' surfaces) the block is represented in the simulations by a single shading surface. In this case the surface used will depend on the value of the [Flat surface position](#) above.

Tip: If your component block has a constant transmittance you can set the transmittance schedule below to **On** and set the constant transmittance for the block here.

For non-flat component blocks every surface is included in the simulation as a shading surface and the solar flux incident upon a building facade will be attenuated by each successive shading object located on a path between the façade and the sun position. The shading transmittance schedule you define is therefore modified to ensure that the overall transmittance of the block is the Maximum Transmittance value multiplied by the schedule you selected. This is done assuming that the component block is convex and that therefore solar rays can only pass through a maximum of 2 surfaces.

Note: In the IDF shading surface data generated for each non-flat component block surface, the transmittance is set to the square root of the Maximum Transmittance value you entered to achieve this.

Non-convex, non-flat component blocks will provide more shading than you specified during times when solar rays pass through more than 2 surfaces.

Transmittance schedule

The component block transmittance schedule defines any time-varying transmittance of the component block surfaces (for EnergyPlus simulations only). By default, the component block is fully opaque for the whole year. The transmittance schedule can contain any value between 0 and 1. The transmittance schedule can be used to allow for seasonal transmittance change, such as deciduous trees that have a higher transmittance in winter than in summer. The table "Modifying Characteristics of Various Species of Trees" in "Landscape Architectural Graphic Standards"• by Leonard J. Hopper, 2007 contains some data on tree solar transmission.

Transmittance based on time of day can also be used - a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.

- For the [daylighting](#) calculation the shading surface's visible transmittance is assumed to be the same as its solar transmittance.
- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note: Shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. So you only need to account for the time-varying transmittance of the shading device in the transmittance schedule, for times whether the sun is up. In other words for times when the sun is not up, it doesn't matter what value of transmittance is contained in the schedule.

Radiance daylighting

Component blocks allow semi-transparent transmission in Radiance daylighting calculations as well as in EnergyPlus. However the Maximum transmittance and Transmittance schedule described above are not used for Radiance daylighting simulations. Instead, the Radiance material properties defined on the Surface properties tab of the Materials dialog are used.

Solar Collector Model Data

[Construction tab](#) in model data under Solar Collector header

Once a solar collector surface has been placed you can define its properties on the Constructions tab under the Solar Collector header.

Solar collector type

You can change the type of solar collector using the drop list. Choose from:

- **1-Solar hot water**,
- **2-Photovoltaic** (PV)

Depending on the type of solar collector selected you will see different data below. For [Solar hot water collectors](#) the only data that can be edited here is the material used to represent the panel in rendered views on the Visualisation tab. All of the rest of the data is defined with the [HVAC Solar collector](#) component and its host loop.

When the **2-Photovoltaic** option is selected further configuration and performance data for the PV panels can be entered as shown in the screenshot below.

Solar Collector	
Solar collector type	2-Photovoltaic
Cost (GBP/m2)	600.000
☒ Shades and reflects	
Level	1-Building
Material	Bitumen Felt
Flat surface position	1-Upper surface
Photovoltaic Options	
Performance type	1-Simple
Performance model	Copy of PV Scheduled Efficiency = 0.15
Heat transfer integration mode	1-Decoupled

Cost

You can define the cost of the collector per area. The units will be the unit of currency currently selected on the Program options dialog per area (e.g. GBP/m2 or USD/ft2).

Costs for the electric distribution can be included separately on the [Load centre](#) dialog.

Level

This setting allows you to associate solar panels with either the building or the site, depending on whether they are attached to the building or a fixed part of the site layout. Most of the time you won't need to change it, but for some simulations it can be important to attach panels to the site rather than the building. For example if you are trying to optimise the orientation of the solar collector using the parametric or optimisation tools, or using the ASHRAE 90.1 automated baseline or UK DSM tools, you should leave panels that are attached to the building structures set to the default building level. However for panels that are *fixed* site objects, you should set these to be site level objects to ensure that they are not rotated with the building as part of any parametric variations.

Select whether the component block is considered to be part of the building or the site, choosing from:

- **1-Building** - the default option where the solar collector is considered to be part of the building and so is rotated with the building as part of parametric and optimisation studies where the [Building orientation](#) is varied.
- **2-Site** - the solar collector is considered to be part of the fixed wider site, perhaps as part of a ground-mounted array and so is not rotated with the building as part of parametric and optimisation studies.

Material

This material is used only to define the texture to represent the Solar collector in rendered views on the Visualisation screen.

Flat surface position

Although solar panels are represented as special types of 3-D component blocks in DesignBuilder modeller, they are simulated as flat (based on the [Maximum flat surface thickness](#) threshold accessible on the Advanced tab of the Model options dialog). You can control how the single surface used to represent a flat solar panel in simulations is defined. Choose from:

- **1-Upper surface**, where the uppermost of the 2 largest solar panel surfaces is used in simulations.
- **2-Lower surface**, where the lowermost of the 2 largest solar panel surfaces is used in simulations.
- **3-Midway surface**, where a surface midway between the lowermost and uppermost large surfaces is used in simulations.
- **4-All surfaces**, this option should not be selected for solar collectors. It is only made available because the same list is used for component blocks. If this option is selected, DesignBuilder will reset it at the solar collector level to **1-Upper surface** at the point of simulation input generation.

Photovoltaic Options

Performance type

Select from:

- **1-Simple**, and
- **2-Equivalent One-Diode**.

Depending on the selection you will be able to select from either a simple or equivalent one-diode definition of the panel.

Tip: PV panels are included in the electrical generation side of the model by specifying them on the [Generator list](#) tab of the Electric load centre dialog when one of the d.c. [Buss types](#) is selected.

Performance model

Choose the component to be used to define the performance of the collector. When the **1-Simple** performance type is selected, select from the list of previously defined [Simple Photovoltaic components](#), or when **2-Equivalent One-Diode** is selected then choose from one of the [Equivalent One-Diode components](#).

Heat transfer integration mode

The PV model allows for different ways of integrating with other EnergyPlus heat transfer surfaces and models and calculating cell temperature. Choose from:

- **1-Decoupled**, where no adjustments are made to account for energy extracted in the form of electricity and the cell temperature of modules in the array is computed based on an energy balance relative to NOCT conditions. Specifically, the cell temperature of the PV is modelled using the method from Duffie and Beckman (1991) for estimating cell temperature.

$$T_c = T_a + \frac{\left(1 - \frac{\eta_c}{\tau\alpha}\right)}{\left(\frac{G_T \tau\alpha}{U_L}\right)}$$

This equation is based upon the standard NOCT (Nominal Operating Cell Temperature) measurements to compute the module temperature T_c at each timestep. The NOCT temperature ($T_{c,NOCT}$) is the operating temperature of the module with a wind speed of 1 m/s, no electrical load, and a certain specified insolation and ambient temperature. The values for insolation, $G_{T,NOCT}$ and ambient temperature $T_{a,NOCT}$ are usually 800 W/m² and 20° C. η_c is the conversion efficiency of the module, which varies with ambient conditions. $\tau\alpha$ is a user-defined constant.

- **2-Decoupled Ulleberg Dynamic**, where the cell temperature is calculated based on a dynamic model developed by Ulleberg in which the cell temperature is a function of the previous cell temperature and the thermal capacity of the PV module material.

$$T_{cell}|_t = T_{ambient} + T_{cell}|_{t-1} - T_{ambient} * e^{\frac{-U_L \Delta t}{Cap}}$$

Note: The above decoupled PV solar panels shade solar radiation from any other building surfaces below so they can be used to model PV shading, awning and the reduced solar gain on roofs where there is a ventilated cavity below the panel. They will be less accurate from the thermal point of view for building integrated PV panels where there is a significant thermal solar gain through the panel and into the building fabric.

Note: Building Integrated PV (BIPV) panels with closer thermal links with the building fabric can be modelled directly on the [Construction](#) and [Glazing](#) dialogs by selecting the appropriate categories. In this case further **Heat transfer integration modes** are allowed.

Modules in parallel

This field is the number of series-wired strings of PV modules that are in parallel to form the PV array. The product of this field and the next field should equal the total number of modules in the array.

The **Modules in parallel** and **Modules in series** data are only used for **2-Equivalent One-Diode** PV arrays.

Modules in series

This field is the number of modules wired in series (on each string) to form the PV array. The product of this field and the previous field should equal the total number of modules in the array.

For more details on the algorithms used for simulation of PV panels see the [EnergyPlus Engineering Reference](#).

See also:

- "How to Model Photovoltaic (PV) Systems" on page 525

PV Generator - Simple

PV Generator Simple component describes a simple model of PV panels that may be useful for early phase design analysis. It provides direct access to the efficiency with which PV panels convert incident solar radiation to electricity and does not require arrays of specific modules to be defined. The full geometric model for solar radiation is used, including shading and reflections to determine the incident solar on the panel. This model is intended to be useful for design purposes to quickly get an idea of the levels for annual production and peak power. The model can also accept arbitrary conversion efficiencies and does not require actual production units be tested to obtain performance coefficients.

Name

This field is the name of the PV array. The name is only used as an identifier.

Fraction of surface area with active solar cells

This field is the user defined fraction for the area of surface named in the parent PV object that will have active PV cells on it. The area actually covered with solar cells will be the net area of the surface (gross area less any sub-surfaces like windows) times the fraction entered here. This fraction includes the difference between PV module area and active cells within it and any losses for how closely packed modules can be arranged on surface. The value should be between 0.0 and 1.0.

Conversion efficiency input mode

This field is used to determine how the thermal efficiency is input. There are two choices

- **1-Fixed** where a constant value for PV electrical conversion efficiency is used.
- **2-Scheduled** where the PV electrical conversion efficiency values are defined in a schedule.

Value for cell efficiency if fixed

This field specifies the efficiency with which solar incident energy is converted to electricity. Efficiency = (electrical power generated [W])/(power of incident solar[W]). These efficiency values are dimensionless and should be between 0.0 and 1.0.

Efficiency schedule

Select the [schedule](#) which specifies dimensionless efficiency values between 0.0 and 1.0. This could be used for example to vary the efficiency to match results computed with more detailed models.

Rated electric power

This numeric field contains the nominal electric power output to be requested from the panel. It is normally equal to the rated power output of the generator (in W or Btu/hr). This value is used only for supervisory control and generator dispatch; the actual power output for each time step is determined by the generator models. This value affects how much a generator is loaded (i.e., requested electric power output) and can also impact the operation of an [electric storage unit](#) if one is connected to the associated [Electric load centre](#).

Note: The **Rated electric power** is used for sizing the battery storage and inverters and does not define the maximum power output available from the panel.

For more details on this input and its relationship with electric storage refer to [Electrical Storage](#) in the EnergyPlus Engineering Reference.

Availability schedule

Select the generator availability schedule. A schedule value of 0 indicates the generator is not available, while a schedule value > 0 indicates that the generator is available to operate.

PV Solar Collector Performance - Equivalent One Diode

This object describes the performance characteristics of Photovoltaic (PV) modules to be modelled using an equivalent one-diode circuit. This model is also known as the 4- or 5-parameter TRNSYS model for photovoltaics.

Note: The number series and parallel-wired of Equivalent One Diode modules to be included in the model are defined on the Constructions tab under the [Solar Collector](#) header.

Technical

Mathematically speaking, the EnergyPlus PV module employs equations for an empirical equivalent circuit model to predict the current-voltage characteristics of a single module. This circuit consists of a DC current source, diode, and either one or two resistors. The strength of the current source is dependent on solar radiation and the IV characteristics of the diode are temperature-dependent. The results for a single module equivalent circuit are extrapolated to predict the performance of a multi-module array.

The module employs a “four-parameter” equivalent circuit to model crystalline (both mono and poly) PV modules developed at the University of Wisconsin – Madison [2]. The values of these parameters cannot normally be obtained directly from manufacturers’ catalogs. However, the PV module will automatically calculate them from commonly available data. The PV module also includes an optional incidence angle modifier correlation to calculate how the reflectance of the PV module surface varies with the angle of incidence of solar radiation.

Equivalent circuit in the four parameter model

More detailed technical information can be found in the EnergyPlus Engineering Reference.

Name

This field contains the unique name for the photovoltaic module performance data. The name is used as an identifier.

Cell type

This field is used to describe the type of technology used in the PV module. There are two options available:

- **1- Crystalline silicon** and
- **2-Amorphous silicon.**

Cells in series

The number of individual cells wired in series to make up a single module. The typical number for a 12V crystalline silicon PV module is 36.

Active area

This field is the active area of the PV module in (m² or ft²).

Transmittance absorptance product

This field indicates the transmittance-absorptance product at normal incidence angles for the PV modules. If the $\tau \cdot \alpha$ product is positive, that value will be used for all angles of incidence. If the value specified is negative, then the magnitude of the given value will be used for normal incidence and the IAM modifier correlation will be used for all other angles.

Semiconductor bandgap

This field is the semiconductor bandgap for the PV material. The bandgap for silicon is 1.12eV (electron volts).

Shunt resistance

This field is the shunt (parallel) resistance (in Ω) in the single diode electrical model of the PV. The shunt resistance is effectively infinite for crystalline silicon based PV modules and is finite for thin film and exotic metal modules.

Reference temperature

This field is the ambient temperature (in K or °F) at reference conditions. The value is usually 298K

Reference Insolation

This field is the radiation level (in W/m² or Btu/h-ft²-°F) at reference conditions. The value is usually 1000 W/m².

Module heat loss coefficient

This field is the heat loss coefficient (in W/m².K or Btu/h-ft²-°F) for the array. The heat loss coefficient is dependent upon measures taken to actively or passively promote airflow over the array surface. The heat loss coefficient value is used only if the Integration and Cell Temperature Mode is set to "Decoupled Ulleberg Dynamic."

Total heat capacity

This field is the heat capacity (in J/m².K or Btu/ft²-F) of the modules in the array. It describes the module's ability to store incident solar radiation internally. Such energy storage is manifested as a temperature increase in the modules that is considered to be undesirable. The total heat capacity value is used only if the Integration and Cell Temperature Mode is set to [2-Decoupled Ulleberg Dynamic](#).

Rated electric power

This numeric field contains the nominal electric power output to be requested from the panel. It is normally equal to the rated power output of the generator (in W). This value is used only for supervisory control and generator dispatch; the actual power output for each time step is determined by the generator models. This value affects how much a generator is loaded (i.e., requested electric power output) and can also impact the operation of an [electric storage unit](#) if one is connected to the associated [Electric load centre](#).

Note: The **Rated electric power** is used for sizing the battery storage and inverters and does not define the maximum power output available from the panel.

For details in this input and its relationship with electric storage refer to [Electrical Storage](#) in the EnergyPlus Engineering Reference.

Availability schedule

Select the generator availability schedule. A schedule value of 0 indicates the generator is not available, while a schedule value > 0 indicates that the generator is available to operate.

Current

Short circuit current

This field is the short circuit current (in A) for an individual module in the PV array at reference conditions.

Module current at maximum power

This field is module current (in A) at the maximum power point and reference conditions.

Temperature coefficient of short circuit current

This field accounts for the fact that the module short circuit current is temperature dependent. The coefficient is given in A/K.

Voltage

Open circuit voltage

This field is the open circuit voltage (in V) for an individual module in the PV array at reference conditions.

Module voltage at maximum power

This field is module voltage (in V) at the maximum power point and reference conditions.

Temperature coefficient of open circuit voltage

This field accounts for the fact that the module open circuit voltage is temperature dependent. The coefficient is given in V/K.

Nominal Operating Cell Temperature

Nominal operating cell temperature test ambient temperature

This field is the ambient temperature (in K or °F) from the Nominal Operating Cell Temperature (NOCT) test. The value is usually 293 K

Nominal operating cell temperature test cell temperature

This field is the cell temperature (in K or °F) from the Nominal Operating Cell Temperature (NOCT) test.

Nominal operating cell temperature test insolation

This field is the insolation level (in W/m² or Btu/h-ft²) from the Nominal Operating Cell Temperature (NOCT) test. The value is usually 800 W/m².

Linear Thermal Bridges At Junctions

[Construction tab in model data under Construction header](#)

You can model linear thermal bridging at junction such as wall to wall corners, wall to floor edges etc using the settings under the **Linear Thermal Bridges at Junctions** header on the Construction tab. These settings are used at zone level and apply to all surface junctions in the zone. Defaults are provided at building and block levels.

The default Psi values in DesignBuilder are the based on BRE IP 1/06 values degraded by the greater of 0.04 W/mK or 50%.

More details on this and how the data relates to the UK NCM can be found in the NCM modelling guide at <https://www.uk-ncm.org.uk/>.

Linear Thermal Bridging at Junctions	
☒ Specify Psi Values	
Psi Values Involving Metal Cladding	
Roof-Wall (W/m-K)	0.420
Wall-Ground floor (W/m-K)	1.730
Wall-Wall (corner) (W/m-K)	0.380
Wall-Floor (not ground floor) (W/m-K)	0.040
Lintel above window or door (W/m-K)	1.910
Sill below window (W/m-K)	1.910
Jamb at window or door (W/m-K)	1.910
Psi Values NOT Involving Metal Cladding	
Roof-Wall (W/m-K)	0.180
Wall-Ground floor (W/m-K)	0.240
Wall-Wall (corner) (W/m-K)	0.140
Wall-Floor (not ground floor) (W/m-K)	0.110
Lintel above window or door (W/m-K)	0.450
Sill below window (W/m-K)	0.080
Jamb at window or door (W/m-K)	0.090

Note: The linear bridging defined by these Psi values is used in Simulations, SBEM and DSM calculations as well as in Heating design and Cooling design calculations.

Specify Psi Values

If you would like to include the effect of thermal bridging in the zone/block/building then check this option and enter the Psi values in the cells below.

Note: Negative psi values can be entered, however if the total zone linear heat conduction rate is calculated as negative it is not included in the model (since EnergyPlus has no concept of negative conduction). In this case a corresponding reduction in surface area must be included manually elsewhere in the zone. The required negative conductance is written out in W/K to the IDF file as a comment.

Reporting

Visualisation

You can obtain a 3D visualisation of the linear thermal bridges applied to the model from the [Model Data tab](#) of Visualisation screen. This enables a visual inspection of the thermal bridges at specific geometric junctions (like wall-to-wall corners) and helps clarify how the various classes of linear bridging are applied to the building geometry.

Heat balance

Note that the bridging component of the heat transfer is not displayed separately in the Heat Balance results displayed on the DesignBuilder results screens when the option is activated. However the total bridging heat transfer for the zone is added into the **Walls** output on the Heating and Cooling design calculations and in Simulation results.

You can obtain a report of the sum of the linear thermal bridging heat conduction for each zone by viewing results using the Results Viewer. To do this look for **Surface Inside Face Conduction Heat Transfer Rate <IDFZoneName> _LINEAR BRIDGE** reports in the Results Viewer report list panel.

EnergyPlus Summary Reports

When checking the **Envelope Summary > Opaque Exterior** tabular data in the [Summary report](#) generated by EnergyPlus, please bear in mind that the small fictitious linear thermal bridging surface areas used in the EnergyPlus linear bridging calculations are included in the reported wall areas. These areas are added to the North-facing surfaces, and the effect on wall areas depends on the Psi values used for the linear thermal bridges.

Psi Values Including Metal Cladding

The Psi values under this header are linear transmittances for junctions where there is metal cladding in a construction on one or more sides of the junction. Metal cladding is important for thermal bridging calculations as junctions involving it tend to create a higher heat flow than those without.

Units are W/m-K or Btu-in/h-ft²-F, i.e. heat flux per length of junction per unit difference in inside to outside temperature.

Definition of Metal cladding

Constructions involving metal cladding are roof or wall systems where metal forms an integral part of the construction, such as metal twin skin systems where the insulation is located between the metal skins and where the metal skins are typically in the range 0.4 mm to 1.2 mm. Cladding with z-spacers would come into this category as would composite metal panel systems.

If the metal is simply used as an external shield against weather, such as a rainscreen, this is not classed, for the purposes of calculations as "metal cladding".

Metal cladding systems are divided into two broad categories, these being:

- a. built up metal cladding systems involving rail and bracket or z-spacer systems with insulation within the panels
- b. composite panel metal cladding systems with insulation inside the panels

You can define whether a construction includes metal cladding on the [Constructions](#) dialog.

Junction type

Roof-Wall

Wall-Ground

Wall-External floor

Description

The average Psi value for junctions between external walls and roofs

The average Psi value for junctions between external walls and ground floors

The average Psi value for junctions between external walls and external floors

Wall-Wall (corner)	The average Psi value for external wall corners. Note that the minimum angular threshold to define a wall-wall corner can be defined under the Advanced header .
Wall-Internal Floor	The average Psi value for junctions between external walls and internal floors. See also Linear bridges shared between 2 zones below.
Wall-External Floor	The average Psi value for junctions between external walls and external floors
Lintel above window or door	The linear transmittance created by lintels above windows and doors
Sill below window	The linear transmittance created by sills below windows
Jamb at window or door	The linear transmittance created by window and door jambs

Psi Values NOT Including Metal Cladding

Definitions for Psi values not including metal cladding are as above.

Technical Note - How it Works

DesignBuilder calculates a total linear bridging transmittance for each zone by summing the bridging length for each of the 14 categories and multiplying each by the user-defined Psi value for that category. The total bridging length is calculated based on the zone outer dimensions.

You must check that you have set the Psi values according to the convention set.

The total zone linear bridging transmittance is included in the EnergyPlus model using a single **WallExterior** surface per zone with fixed interior and exterior convection coefficients of 3 and 25 W/m²K for the interior and exterior sides of the surface respectively. Visible, solar and thermal heat transfer is effectively zero through use of zero of absorptance values. The material layer used in the wall has a resistance of 0.6267 m²K/W. Note that the overall resistance of the wall construction (**LinearBridgingConstruction**) including the layer and the film convective resistances is approximately 1 m²K/W, i.e. a conductance of 1 W/m²K.

The area of each **WallExterior** surface is calculated so that its total conductance (W/K) is the same as that of the sum of the zone linear bridges. To achieve that the height of each surface is set to 1m and **the total zone linear bridging conductance is written to the Length field**. This results in the user-specified linear bridging conductance being applied in the simulation at all timesteps.

The linear bridging **WallExterior** surfaces are located below the building to avoid interfering with shading calculations.

Note: When checking the "Envelope Summary, Opaque Exterior" tabular data in the Summary report generated by EnergyPlus, please bear in mind that these fictitious surface areas are included. This can cause a small inaccuracy in reported wall areas.

Advanced

Angular threshold for Wall-Wall corners

This threshold defines the minimum angular deviation from coplanar that is considered to be a corner in the calculation of Wall-Wall linear thermal bridging.

For example if the threshold is entered as 22.5° (the default) and 2 adjoining external walls meet with a difference of 20° relative to coplanar (see schematic below) then no thermal bridge will be included for this corner. However, if the angular difference between the 2 walls was 30° then a thermal bridge would be included.

Linear bridges shared between 2 zones

In cases where a linear bridge is shared between two zones, for example the bridge between an external wall and an interior floor, any additional thermal conductance caused by such bridges is shared between the two zones involved. Put another way, thermal bridging lengths and Psi values cover both sides, and half the heat transfer is applied on each side. You must take this into account when entering Psi values for such bridges.

Baffle

[Construction tab](#) in model data under [Construction header](#)

You can model a multi-skin exterior heat transfer surface by making settings on the Constructions tab under the **Baffle** header at surface level. Baffle components consist of an outside baffle surface which is slightly detached from the main wall or roof forming a cavity which exchanges air with the outside environment.

Baffles are typically used to model naturally ventilated rainscreens and/or solar shading of exterior surfaces.

The constructions used to define the underlying wall/roof should reflect the construction of just the underlying surface. The data described here is used to describe the decoupled baffle layer and the characteristics of the cavity and openings for natural ventilation.

Tip: If the baffle covers only part of a surface, then surfaces without the baffle can be modelled as sub-surfaces which do not have natural vented cavities.

Tip: You can enter corresponding data for natural vented cavities on the Construction template dialog. If you need to apply settings to a large number of surfaces you may find the fastest way to do this is to use the [Load data from template](#) dialog, selecting the surfaces which have a baffle on the Target tab and selecting the Construction template with the appropriate natural vented cavity and construction settings.

Technical Notes

1. The corresponding EnergyPlus object is **SurfaceProperty:ExteriorNaturalVentedCavity**.
2. The heat capacity of the outer baffle is ignored in the simulation since it is much lower than that of the underlying mass surface.
3. The model involves predicting the rates that ambient air moves in and out of the cavity. Accurate modelling of these air flows would be extremely challenging and so the models provided through this object are simplistic engineering models based on discharge coefficients that are sensitive to wind and buoyancy effects. The accuracy depends on the values for, and applicability of, the discharge coefficients and unfortunately little research is available to help characterize these. The models should be considered rudimentary and the user is encouraged to explore different values for the coefficients in attempts to bound the importance of natural ventilation for the cavities. See the [Engineering Reference](#) for more details.

Area fraction of openings

This field is used to enter an area fraction for what part of the baffle consists of openings. The area of the openings will set to the product of this field and the sum of the area of the underlying surfaces.

Thermal emissivity of exterior baffle material

This field is used to enter the thermal emissivity of the baffle. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

Solar absorptivity of exterior baffle

This field is used to enter the solar absorptivity of the baffle. This surface property is for shortwave, solar radiation. The property is used for the front side of the baffle that faces the environment. Darker colors have a higher absorptivity. While black is the highest performance, other colors might be used to match the colour scheme of the rest of the façade.

Height Scale for buoyancy-driven ventilation

This field is used to enter a nominal height scale (m) for prediction of ventilation induced by buoyancy. This value () is defined as the height from the midpoint of the lower opening to the neutral pressure level. Increasing the value will increase the ventilation rate due to buoyancy.

Effective thickness of cavity

This field is used to enter a nominal gap thickness (m) for the collector. If the baffle is corrugated, use the average depth. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

Ratio of actual to projected surface area

This field is used to enter a factor that accounts for the extra surface area resulting from an uneven baffle surface. Corrugations may be present to help stiffen the baffle or ventilated roofing tiles may have more surface area for convection heat transfer than the underlying surface. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the baffle is flat then this ratio is 1.0. If the baffle is corrugated, then this ratio will be greater than one with a typical value might be 1.165.

Roughness of exterior surface

This field is used to describe the relative roughness of the baffle material which influences the exterior convection coefficient. Select from:

- 1-Very rough
- 2-Rough
- 3-Medium rough
- 4-Medium smooth
- 5-Smooth
- 6-Very smooth

Effectiveness for perforations with respect to wind

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind. Wind will cause exterior air to move in and out of the cavity. C_v is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind. C_v should probably be in the range 0.05 to 0.65. Increasing C_v will increase the amount of natural ventilation. The following equation shows how C_v is used in the program to predict the volumetric flow rate due to wind:

$$\dot{V}_{\text{wind}} = C_v A_{\text{in}} U_{\infty}$$

Discharge coefficient for openings with respect to buoyancy driven flow

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy. Stack or buoyancy effects will cause exterior air to move in and out of the cavity. C_d is an arbitrary discharge coefficient that depends on the geometry of the opening. C_d should probably be in the range 0.1 to 1.0. Increasing C_d will increase the amount of natural ventilation. The following equations show how C_d is used in the program to predict the volume flow rate due to buoyancy:

$$\dot{V}_{\text{thermal}} = C_D A_{\text{in}} \sqrt{2g \Delta H_{\text{NPL}} (T_{a,\text{cav}} - T_{\text{amb}}) / T_{a,\text{cav}}} \quad (\text{if } T_{a,\text{cav}} > T_{\text{amb}})$$

$$\dot{V}_{\text{thermal}} = C_D A_{\text{in}} \sqrt{2g \Delta H_{\text{NPL}} (T_{\text{amb}} - T_{a,\text{cav}}) / T_{\text{amb}}} \quad (\text{if } T_{\text{amb}} > T_{a,\text{cav}} \text{ and baffle is vertical})$$

where ΔH_{NPL} is the value input into the field above for the height scale for buoyancy-driven ventilation.

Ground Modelling

[Construction tab](#) in model data under [Construction header](#)

Kiva

If the site level [Ground modelling method](#) is set to **4-Kiva Full** then options are made available on the Constructions tab for surfaces in contact with the ground and also at building, block and zone levels for setting defaults for ground-adjacency surfaces.

Kiva adjacency

If you are at surface level and the current surface has an adjacency to a [Kiva foundation](#) then check this checkbox. If you are at building, block or zone level then you can use this checkbox to set the default if the majority of the ground adjacent surfaces in that object have an adjacency with a Kiva foundation.

Tip: If all (or most) ground-adjacent floors and walls in the building are to be linked to Kiva foundations then you should check this option at building level and select the most commonly used Kiva foundation (below).

Kiva foundation

If you are at surface level and the above Kiva adjacency checkbox is checked then select the appropriate [Kiva foundation](#). If you are at building, block or zone level then you can use this checkbox to set the default Kiva foundation.

Ground Domain

If the site level [Ground modelling method](#) is set to **3-Ground domain** then an option will be available on the Constructions tab for surfaces in contact with the ground and also at building, block and zone levels for setting defaults.

Define ground domain

Select the type of [ground domain](#) that the surface is in contact with from the list:

- **1-No ground domain** - the surface is not in contact with a ground domain. Instead the conditions on the other side of the surface are defined using the default ground temperature mechanism using [Ground monthly temperatures](#).
- **2-Slab** - the horizontal surface is in contact with a slab ground domain object.
- **3-Basement** - the underground surface is in contact with a basement ground domain object.

Ground domain

Select the [ground domain](#) in contact with this surface from the drop list of available domains.

Tip: Domain-surface connection settings can be made at any of building, block, zone and surface levels. Setting data at building, block or zone level provides a quick way to associate multiple ground adjacent surfaces to a single ground domain.

Ground Domain Slab Tutorial

This tutorial takes you through the basic steps of adding a single [ground domain](#) to an existing single zone model. It illustrates the process involved in adding a ground slab with vertical and horizontal insulation. The objective is to model a case like that illustrated schematically below.

Data Entry

1. Create a single zone model 10m x 20m with the longest dimension on the E-W axis as shown below. Use default settings throughout including the default London Gatwick location.

2. The first step in setting up a ground domain is to navigate to site level and on the Location tab, open the [Site Details](#) header and also the Ground and [Ground Modelling](#) headers.

3. Select the **3-Ground domain** [Ground modelling method](#).

4. To model a single ground slab set the **Number of ground domains** to 1 and copy the "Default Slab" Ground domain to create an editable copy for working with. Name it "Project Slab" and select it. Your screen should now look something like the screenshot below.

Location Template		▼
Template		LONDON/GATWICK ARPT
Site Location		>>
Site Details		▼
Elevation above sea level (m)	62,0	
Exposure to wind	2-Normal	▼
Site orientation (°)	0,0	
Site Height Variation		>>
Ground		▼
Surface		>>
Ground Modelling		▼
Ground modelling method	3-Ground domain	▼
Number of ground domains	1	▼
Ground domain 1	Project Slab	

5. Now edit the "Project Slab" Ground domain, making the following changes:

- On the [General](#) tab:

- Set **Slab location** to **2-In grade**.
 - Set **Slab material** to "Cast Concrete (Dense)"
 - Set Slab **Thickness** to 0.1m
 - Set the **Aspect ratio** to 2, calculated as the aspect ratio of the 20:10 length:width aspect ratio of the building perimeter.
 - Set **Perimeter offset** to 5m.
- b. On the [Soil](#) tab, select the Soil material to be "Earth, Common".
 - c. On the [Ground Undisturbed Temperatures](#) tab set the **Ground undisturbed temperature type** to **1-Finite difference**. This allows EnergyPlus to calculate the undisturbed temperature boundary conditions for the Ground domain and no ground temperature data needs to be entered.
 - d. On the [Insulation](#) tab, check the **Include horizontal insulation** checkbox.
 - e. Under that checkbox:
 - Select the horizontal insulation **Material** to be "EPS Expanded Polystyrene (Heavyweight)".
 - Set the **Thickness** to be 0.1m.
 - Set the **Extent** to be **2-Perimeter**, i.e. the slab is only insulated around its perimeter. Note that this setting may not be realistic for a new build in the UK, but it illustrates a powerful capability of the Ground domain slab modelling capability. The effect of using **1-Full** extent is also tested in the next section.
 - Set the **Perimeter insulation width** to 1m.
 - f. Also check the **Include vertical insulation** checkbox, then:
 - Select the vertical insulation **Material** to be "EPS Expanded Polystyrene (Heavyweight)".
 - Set the **Thickness** to be 0.1m.
 - Set the **Depth** to 1m.

Data on the Insulation tab should now look like the screenshot below:

Ground Modelling	
General Soil Ground Undisturbed Temperatures Insulation	
Horizontal Insulation	
☒ Include horizontal insulation	
Material	EPS Expanded Polystyrene (Heavyweight)
Thickness (m)	0.10000
Extent	2-Perimeter
Perimeter insulation width (m)	1.000
Vertical Insulation	
☒ Include vertical insulation	
Material	EPS Expanded Polystyrene (Heavyweight)
Thickness (m)	0.10000
Depth (m)	1.000

The meaning of the various thicknesses, depths and offsets defined above can be seen in the schematic diagram at the [top](#) of this article.

6. Navigate to the Ground floor surface, open the **Construction** tab and open the **Ground Modelling** header.
7. Click on **Define ground domain (for floor)** and select **2-Slab**.
8. To associate the Project Slab ground domain that you have defined above with the ground floor surface, set the **Ground domain** to **1-Project slab**. The Constructions tab for the ground surface should now look like the screenshot below.

Note: Because this is a single zone model with a single ground floor, you could equally make this setting at building, block or zone level. For a larger model whose ground domain definition is the same for all ground floors you may prefer to make this setting at building level.

9. Because we are using the **2-In-grade** ground domain option, the ground floor construction must not include the slab, insulation or earth, so the default ground floor construction must be updated to reflect this rule. Edit the default "Project ground floor" construction by removing the insulation and cast concrete layers. The construction dialog should look like the screenshot below:

That completes the main part of the model set up and you are now ready to run simulations.

Simulations

We will run 5 annual simulations to help us understand the impact of some key changes to the model. Please read all of this section before running any simulations.

- 1m insulation depth (vertical) and 1m perimeter insulation width (horizontal), the configuration defined above.
- 2m insulation depth (vertical) and 2m perimeter insulation width (horizontal). To set this up open the "Project Slab" Ground domain dialog, click on the Insulation tab and change both the horizontal **Perimeter insulation width** and vertical **Depth** to 2m.
- The same configuration as defined for simulation 1, but with the horizontal insulation extent set to **1-Full**.
- No insulation. To set this up open the "Project Slab" Ground domain dialog, click on the Insulation tab and uncheck the **Include horizontal/vertical insulation** checkboxes.
- No ground domains, reverting to the standard monthly ground temperature approach. To set this up:
 - Select the **1-Standard** Ground modelling method option to simulate the ground floor heat flow in 1-D using an adjacency to the site level **Ground monthly temperatures**.
 - Add 0.1m of "EPS Expanded Polystyrene (Heavyweight)" insulation and 0.1m "Cast Concrete (Dense)" layers to the ground construction that were removed in step 9 of the Data Entry section above to ensure that we roughly compare like with like.

Ensure that the **Surface heat transfer** output option is checked before running any simulations so that ground heat transfer data is generated to help us compare the 5 options.

Use the **Simulation Manager** to run the simulations and give the simulations appropriate descriptions to ensure that results are labelled correctly when we view them in the ResultsViewer.

Viewing Results

When you have finished running the 5 simulations, open the Simulation Manager and select the 5 simulation result sets. Then click on the toolbar icon to compare the results in ResultsViewer as shown below.

In ResultsViewer, with the results loaded, click on the **Monthly** tab, select the ground floor heat loss Report Type and click on the **Add selected variables to new graph for all datasets** toolbar icon as shown below.

You should see results similar to those below.

Notes on the Results

1. The heat loss results from the case with most extensive insulation: "1m insulation depth (vertical) and horizontal extent set to 1-Full" gives the lowest heat loss over the year (yellow line).
2. Replacing the full horizontal insulation with 2m perimeter insulation gives the next lowest floor heat loss (purple line).
3. Reducing the perimeter insulation further to 1m gives the next lowest heat loss (orange line).
4. Removing all insulation increases heat loss as expected (green line).
5. For the no ground domain case, the results are (perhaps not surprisingly) very different from the other simulations that do use the ground domain. The uninsulated ground floor is directly exposed to the default constant 18°C monthly ground temperatures and heat flows are much lower.

- Results for Jan are *very* different from those for December which suggests that the 1 year simulation we used here was not enough to ensure correct initialisation of the ground domain temperature field. This is addressed in the next section.

The tutorial demonstrates how spending a few minutes setting up a slab ground domain allows us to model the ground heat loss in a much accurate way than using the basic default 1-D method.

Simulation Using Multiple Years

Ground domains can take a long time to establish a realistic temperature field so, for the best accuracy, you should run simulations for more than one year. DesignBuilder allows any number of years to be simulated by checking the **Run simulation for multiple years** option on the **Simulation calculation options** dialog and entering the number of years.

The next part of the tutorial shows you how to run multi-year simulations and check results. Follow the steps below.

- Ensure that the model is configured per the original settings, case 1 under the [Simulations section](#): 1m insulation depth (vertical) and 1m perimeter insulation width (horizontal), then run a simulation for 5 years, as described above. This takes longer than you might expect for this simple building because the ground domain is being simulated in 2-D over a 5-year period.
- When the simulation has finished load the results into DesignBuilder.
- Navigate to building level, select the **2-Monthly** interval and **5-Fabric and ventilation** data and Show as **1-Graph** options. If you also deselect the other fabric and ventilation data using the checkboxes on the Detailed tab of the Display options panel, you should see an output similar to the one below.

Note: The important learning point from this analysis is that when only running a 1 year ground domain simulation, the ground heat loss in the first month of the simulation is much higher than in subsequent years due to the inadequately formed ground temperature field in the first year. Running simulations for multiple years and only using results for the last year gets around this issue by ensuring a more accurate initialisation of the ground temperature field.

Airtightness

[Construction tab](#) in model data

There are two ways of defining air tightness depending on the Natural ventilation model option:

- [Scheduled](#)
- [Calculated](#)

In both cases infiltration can be switched off at building, block or zone level.

Airtightness (Scheduled Natural Ventilation)

[Construction tab](#) in model data under [Airtightness header](#)

Model infiltration

Infiltration is included by default but you can switch infiltration off by unchecking the **Model infiltration** checkbox.

Infiltration rate

With the Scheduled natural ventilation option set, the design infiltration rate (rate of entry of unintentional air from outside through cracks, holes and through the porosity of the fabric) is assumed to be constant throughout the simulation though it can vary with time through a [schedule](#) and it can also be made to vary according to simple rules based on temperature difference between inside and outside and wind speed.. The design infiltration rate can be set in one of 4 different units depending on the setting of the [Infiltration units](#) model option:

1. **ac/h** - the default option where infiltration is defined in air changes per hour (ac/h), i.e. zone volume per hour under standard operating pressures. An input value is entered equivalent to the actual anticipated air changes due to infiltration during normal operation under typical pressures, not under pressure test conditions. It will operate according to its schedule (below). Note that if you input a value of 0.6 (and assuming a schedule value of 1) then in the outputs you will see 0.6 +/- a small amount as the air temperature (and hence density) varies slightly.
2. **m3/h-m2 at 50 Pa** infiltration is defined as flow rate in m3/h per unit exposed surface area, when the pressure difference between inside and outside is 50 Pa. Unit commonly used in the UK. Note that this is a rate under pressure test conditions and therefore the actual rate under normal operating conditions (at much lower pressures) will be a lot lower.
3. **m3/h-m2 at 4 Pa** infiltration is defined as flow rate in m3/h per unit exposed surface area, when the pressure difference between inside and outside is 4 Pa. Units commonly used in France and Belgium. DesignBuilder calculates the actual resultant value under Standard Pressure of 1atm or 101325 Pa using formulae from EN12831 (section 7.2.2):
4. **n50 - ac/h at 50 Pa** - infiltration is defined in air changes per hour (ac/h), i.e. zone volume per hour, when the pressure difference between inside and outside is 50 Pa. Unit commonly used in Europe. When this option is selected there are options to override the default EN 12831 wind exposure and building height coefficients to account for national standards. See below under [Coefficient Override options for "n50 - ac/h at 50 Pa"](#).

Technical Notes

This note describes the methods used to convert entered infiltration values described above to the m3/s value provided to EnergyPlus. The equation used depends on the units selected as follows.

2-m3/h-m2 at 50 Pa

$ac/h = 2 \text{ (m3/hr-m2 at 50 Pa) (Exposed_Area) (EI) (Epsilon) / (Zone_Volume)}$

3-m3/h-m2 at 4 Pa

$ac/h = 2 \text{ (m3/hr-m2 at 4 Pa) (Exposed_Area) (EI) (Epsilon) / (0.18566355 (Zone_Volume))}$

4-n50 - ac/h at 50 Pa

$ac/h = 2 \text{ (n50 - ac/h at 50 Pa) (EI) (Epsilon)}$

The air flow rate in m³/s at standard pressure provided to EnergyPlus is calculated from the ac/h calculated above using:

$$\text{m}^3/\text{s} = (\text{ac}/\text{h}) (\text{Zone_Volume}) / 3600$$

where **Zone_Volume** is the air volume of the space calculated based on the [Zone volume calculation method](#) selected under "Geometry Areas and Volumes" on page 366

The **Exposed_Area** value is the sum of the gross area of the zone exterior surfaces, excluding any ground and adiabatic surfaces. That includes external walls, flat and pitched roofs, external floors and all external windows. It does not include ground floors, semi-exposed or adiabatic surfaces.

Epsilon is the building height class and accounts for height of building. It is calculated by DesignBuilder based on the building height using EN12831 rules:
epsilon:

- 0-10m = 1
- > 10-30m = 1.2
- > 30m = 1.5

The **EI** wind exposure class [coefficient] is determined based on the façade exposure of each zone and the [Exposure to Wind](#) setting according with the table from EN12831 below.

Exposure to Wind	Exposure description	Heated zone no façade exposed to outside	Heated zone with single façade exposed	Heated zone with multiple façades exposed
3-Exposed	Open site (sea shores, open country...)	0.01	0.03	0.05
2-Normal	Medium sheltered site (towns, city periphery)	0.01	0.02	0.03
1-Sheltered	Well sheltered site (city centre)	0.01	0.01	0.02

Note that the above EN 12831 Epsilon and EI values can be overridden for the **4-n50 - ac/h at 50 Pa** option. [See below.](#)

Coefficient Override options for "n50 - ac/h at 50 Pa"

Override wind exposure coefficient

Some national standards require a fixed value of wind exposure coefficient to be used instead of the default from EN 12831. To override the default, check this checkbox and enter the required coefficient in the text box below.

Wind exposure coefficient

Enter the wind exposure coefficient to override the default value from EN 12831.

Override height coefficient

Some national standards require a fixed value of building height coefficient to be used instead of the default from EN 12831. To override the default, check this checkbox and enter the required coefficient in the text box below.

Height coefficient

Enter the height coefficient to override the default value from EN 12831.

Schedule

The [schedule](#) that modifies the design infiltration rate. The schedule should contain fractions between 0.0 and 1.0 and is used for Cooling design and Simulations (when the Scheduled natural ventilation option is set) but not for Heating design calculations which use a constant design infiltration rate. The exact usage of this schedule (F_{schedule}) is shown in the equation in the section below.

Note: Both the [Infiltration rate](#) and [Schedule](#) are only used in Simulations when the Scheduled natural ventilation model option is set. However this data is still used when Calculated natural ventilation is set for Cooling design calculations (Infiltration rate and schedule) and Heating design calculations (Infiltration rate only).

DeltaT And Wind Speed Coefficients

During the simulation, the infiltration flow of outside air into the zone is calculated for each timestep from the equation below:

$$\text{Infiltration} = (I_{\text{design}})(F_{\text{schedule}})[A + B |(T_{\text{zone}} - T_{\text{outside}})| + C (\text{Wind Speed}) + D (\text{Wind Speed})^2]$$

The coefficients A, B, C and D can be defined by entering data for the 4 fields described below.

By default A is 1 and B, C and D are 0 so that the infiltration rate is calculated simply as the entered design infiltration flow rate value multiplied by the schedule value (0 - 1), unmodified by temperature difference or wind effects. However if you need to model the impact of inside to outside temperature difference or wind speed in a simple way then you can enter appropriate values for terms, A-D as described below.

More advanced infiltration calculations are possible using [Calculated natural ventilation](#) through the EnergyPlus AirflowNetwork model for natural infiltration driven by wind when the HVAC system does not operate and/or driven by wind and forced air for times when the HVAC system operates. Exfiltration (the leakage of zone air to the outside) is generally handled better as zone exhaust air in the zone equipment description.

Technical Notes

The question of typical values for these infiltration coefficients is subject to debate. Ideally, one should do a detailed analysis of the infiltration situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. As previously noted, the defaults are 1,0,0,0 which gives a constant volume flow of infiltration under all conditions.

BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0°C deltaT and 3.35 m/s (7.5 mph) wind speed, which corresponds to a typical summer condition. At a winter condition of 40°C deltaT and 6 m/s (13.4 mph) wind speed, these coefficients would increase the infiltration rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (wind speed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A wind speed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as:

“Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions.”

The source of the DOE-2 defaults is based on examining the infiltration relationships described in the ASHRAE Handbook of Fundamentals.

The EnergyPlus example files use all of the above, the BLAST defaults in some (e.g., GeometryTest), the DOE-2 defaults in some (e.g., 5ZoneAirCooled), and the EnergyPlus defaults in some (e.g., LgOffVAVDetCoil).

Constant

The constant term, A, in the above equation, set to 1 by default.

Temperature

The temperature difference term, B, in the above equation, set to 0 by default.

Velocity

The velocity term, C, in the above equation, set to 0 by default.

Velocity squared

The velocity squared term, D, in the above equation, set to 0 by default.

Airtightness (Calculated Natural Ventilation)

[Construction tab](#) in model data under [Airtightness header](#)

Model infiltration

Infiltration is included by default but you can switch infiltration off by unchecking the **Model infiltration** checkbox. This may be useful if you are carrying out a calculated natural ventilation summertime simulation of a large building to reduce the number of cracks in the model and so speed simulations.

Note: if you switch off infiltration when Calculated natural ventilation is active, you should make sure that the [Natural ventilation](#) option on the HVAC tab is switched on to ensure that sufficient flow paths exist. Otherwise EnergyPlus may generate errors.

Calculated Natural Ventilation

When [Calculated](#) natural ventilation is active, the Airtightness is defined through a crack template. Depending on the [Airtightness method](#) model option there are 2 different ways to define the airtightness of the building:

- **1-Template slider.**
- **2-Crack template.**

These options are used as follows.

Template slider

Airtightness is defined through a five point scale:

The five settings correspond to 5 pre-defined [Crack templates](#).

Crack template

When the **2-Crack template** [Airtightness method](#) is used, airtightness is defined through a specific selection of a template which can be user-defined. With this method it is still possible to select the pre-defined crack templates referred to by the **Template slider** method.

Infiltration airflow calculations

When using Calculated natural ventilation there are 2 main categories of uncontrolled infiltration airflow:

- Airflow through the surface itself which could be caused by cracks or by general fabric porosity.
- Cracks between windows, vents and doors and the main wall or roof surface.

The data that allows DesignBuilder to generate these airflow paths is stored in Crack templates. For example, take a 20m² external wall with a single 2m x 1m window. If the **Good** crack template is selected for the surface then the flow paths used in the simulations will be as follows:

1. Main surface infiltration 0.000040 kg/s.m² @ 1Pa, which for the 18m² (20m² - 2m²) wall = 0.0072 kg/s @ 1Pa.
2. In the **Good** Crack template, cracks between windows and walls have infiltration 0.000060 kg/s.m @ 1Pa. Our window has perimeter 6m so the overall crack property used in the simulation would be 0.00036 kg/s @ 1Pa.

The screenshots below indicate the source of the above Crack template values.

Cracks Data	
General Openings Walls Floors/Ceilings Roofs	
Windows	
External	
Flow coefficient (kg/s.m crack @ 1Pa)	0.000060
Flow exponent	0.70
Internal	
Flow coefficient (kg/s.m crack @ 1Pa)	0.000600
Flow exponent	0.70
Doors	
External	
Flow coefficient (kg/s.m crack @ 1Pa)	0.000600
Flow exponent	0.70
Internal	
Flow coefficient (kg/s.m crack @ 1Pa)	0.020000
Flow exponent	0.70
Vents	
External	
Flow coefficient (kg/s.m crack @ 1Pa)	0.004000
Flow exponent	0.66
Internal	
Flow coefficient (kg/s.m crack @ 1Pa)	0.003000
Flow exponent	0.60

External window crack data in Crack template dialog

Cracks Data

General Openings **Walls** Floors/Ceilings Roofs

Walls

Internal

Flow coefficient (kg/s.m2 @ 1Pa) 0.002000

Flow exponent 0.75

External

Flow coefficient (kg/s.m2 @ 1Pa) 0.000040

Flow exponent 0.70

External wall crack data in Crack template dialog

Note: As well as being included in standard simulations, infiltration from Calculated natural ventilation is also included in Detailed HVAC autosizing calculations and also in Simple HVAC sizing when using the [2-EnergyPlus Simple HVAC autosizing method](#).

Scheduled Natural Ventilation + Heating And Cooling Design Calculations

Constant rate

Enter the maximum rate of infiltration, which is modified by the multiplier fraction factors in the Schedule select below. The units for the infiltration depend on the [Infiltration units](#) Model data setting. This value and the associated schedule below are used for Cooling design calculations as well as simulations when using Scheduled natural ventilation.

Note: for zones that are below ground level you should set the infiltration rate to zero if there is no external air entering through cracks/porosity. Such zones shouldn't receive any infiltration during the simulation when calculated natural ventilation is set because the "external" surfaces will be adjacent to ground, but this does need to be set manually for heating and cooling design purposes.

Schedule

Select the schedule which defines any time-varying of the infiltration. The default schedule is **On** giving a constant infiltration rate based on the Constant rate entered as described above.

Construction Cost

[Construction tab in model data](#)

Additional cost data can be defined for each zone and surface using the controls under the Cost header on the Constructions model data tab.

Tip: The [Cost data](#) help topic provides an overview of the places in DesignBuilder where costs are entered.

Sub-Structure cost

In general the sub-structure cost is the cost of all works below ground level. The sub-structure cost data entered here is used at zone level and is multiplied by the zone sub-structure surface area, which is calculated as the sum of all ground floor areas in the zone, i.e. the sum of all floors with a ground adjacency.

Note: Additional substructure cost is included in below grade surfaces and their constructions.

Structure

Select the structure type to define the cost of the building structural elements per floor area. This data is used zone by zone when calculating total building structural costs. Structure costs appear in the report, depending on the [cost model](#) used, as follows:

- Basic: Structure costs
- UNIFORMAT II: **B20 Exterior enclosure** Group Element report section
- NRM1: Super Structure

Cost Of Internal Finishes

Walls

Enter the cost of internal finishes for all walls (external and internal partitions) in cost per surface area. This should cover the cost of paint, wallpaper or any other material or process not already covered in the wall construction costs.

Floors

Enter the cost of internal finishes for all floors (external, ground and internal) in cost per surface area. This should cover the cost of paint, polish or any other material or process not already covered in the floor construction costs.

Ceilings

Enter the cost of internal finishes for all ceilings (internal and underside of external roof surfaces) in cost per surface area. This should cover the cost of paint, polish or any other material or process not already covered in the ceiling/roof construction costs.

Openings Model Data (Windows, Doors, Vents, Holes, Sub-surfaces)

[Openings tab in model data](#)

The term **opening** is used in DesignBuilder to describe any opening in the main building fabric. These are modelled as exceptions to the main surface construction. There are five types of opening:

- Windows
- Sub-surfaces (i.e. opaque elements within the surface that have different properties from the main construction. For example lintels and lightweight panels can be defined as sub-surfaces. Data for these is held on the [Construction tab](#))
- Holes
- Doors
- Vents

The layout, operation and construction data for these (apart from sub-surfaces) can be set on the Openings tab.

See also the [Glazing and openings](#) and [Drawing windows and doors](#) tutorials

Templates

You can load generic Opening data by clicking on the Template option under Glazing Template and then by clicking on the '...' at the right of the line (below).

When you make a selection from the list of [Glazing templates](#), data from selected template will be loaded to the model.

You can also open the:

- [External Glazing](#)
- [Internal Glazing](#)
- [Roof Glazing](#)
- [Doors](#)
- [Vents](#)

headers to enter opening details where they are different from those loaded from the template.

Note: Once you have created custom openings on any particular surface, changes made to facade layout on this tab will not affect the layout for the surface.

All Openings data is used to generate simulation data at the **Surface level**.

You can also override default [Pressure Coefficient](#) data when the Calculated Natural ventilation option is set and you are at surface level.

External Glazing

[Openings tab](#) in model data

The data under the External Glazing header applies to all glazing lying on external walls. You can enter information on:

- [Dimensions](#)
- [Frame](#)
- [Shading](#)
- [Operation](#)

Dimensions (Walls)

[Openings tab](#) in model data under External Glazing and Internal Glazing headers

You can use settings such as **Window to wall %** (WWR) and **Window height**, [Window spacing](#) and [Sill height](#) to easily change the amount of glazing and its layout on the walls. The way this data is used for each façade type is described below.

Facade types

There are a number of standard façade types:

- **0-None** - there is no glazing.
- **1-Continuous horizontal** - glazing is generated in a continuous horizontal strip using Sill height, Window spacing and Percentage glazing.
- **2-Fixed height** - glazing is generated with a fixed height at the specified Sill height and Window spacing, and width is calculated based on the Percentage glazing. This option uses **Window to wall %** but prioritises window height.
- **3-Preferred height** - glazing is generated using the window height data and the Percentage glazing, but the Window height may be adjusted to achieve the required **Window to wall %**. This option uses Window height, Window spacing and Sill height but prioritises **Window to wall %**.
- **4-Fixed width and height** - windows have fixed width and height.
- **5-Fill surface (100%)** - the entire surface is filled with glazing and there is **no frame**.

Window to Wall %

Often referred to as the Window to Wall Ratio (WWR) this setting is a fundamental parameter in DesignBuilder used to control the proportion of glazing on building façades. It can be used to change the amount of glazing for all openings at or below the current level in the building hierarchy. For example changing the WWR at building level changes the size of all windows in the model not overridden by other settings lower in the hierarchy.

When using the **2-Outer volume** [Zone geometry and surface areas](#) option (typically one of the "External measurements" convention templates) it is important to understand that the reference surface area used when calculating the window area from the % value supplied is based on the [Window to wall ratio method](#) which is accessed from the Constructions tab under the "Geometry Areas and Volumes" on page 366header.

The image below illustrates a wall in a model using the "External measurements" geometry convention template where a window has been created using the **3-Preferred height** façade option with a 10% glazing ratio. You can see the black outline showing the available area where the window could possibly be sited. Areas outside this outline to the left and right are taken up by corners with adjacent walls. The % glazing calculation uses the black outline area as the reference area. In an extreme case where 100% glazing is specified the whole of this area would be filled with window, but of course the sides of the surface where there is a corner with an adjacent surface cannot contain a window and so do not take part in the calculation - even though they will form part of the surface used in the simulation.

Tip: If you need to ensure that the % window areas used in the simulation exactly match the % you define here then you should consider using the [Simple Geometry convention template](#) which ensures that 100% of each surface is available for containing windows by using zero surface thickness for all surfaces.

Note: If any custom windows are drawn on a surface, the automatic (aka default) façade mechanism described on this page using Window to Wall % (WWR), window width, height, spacing etc is not applied any more. The façade mechanism can be reinstated using the [Clear data to default](#) option. For more information see expanding text below.

Window to Wall %, Custom Facades and Parametric Tools

The behaviour of the WWR % setting changes significantly when custom windows are introduced. This section explains how WWR % operates in DesignBuilder and its interaction with custom windows, especially in the context of using parametric tools.

How WWR % Functions in DesignBuilder

- **Default Façade Mechanism**
WWR % automatically sizes and places windows on building façades based on the specified ratio. This setting can be applied at building, block, zone, and surface levels.
- **Parametric Tools:**
WWR % is commonly used as a variable in parametric studies to evaluate the impact of different glazing ratios on building performance.

Impact of Using Custom Windows

- **Override of Default Mechanism:**
When you manually draw or size windows (custom windows) on a surface, the automatic façade mechanism—including WWR %, window width, height, and spacing—is disabled for that surface.
- **WWR % Not Applicable:**
For surfaces with custom windows, changes to the WWR % setting will not affect those windows. Only the manually defined windows are considered in calculations.
- **Restoring WWR % Control:**
To re-enable WWR % control, use the “Clear data to default” option. This removes custom windows and reinstates the automatic façade mechanism.

Practical Implications for Parametric Calculations

- **If your parametric study relies on varying WWR %:**
 - WWR % will only affect surfaces without custom windows.
 - Custom windows remain fixed in size and position, regardless of WWR % changes during parametric runs.
- **To ensure WWR % is applied throughout your model:**
 - Avoid drawing custom windows, or clear them before running your parametric analysis.
 - Use the default façade settings to allow WWR % to control window area and placement.

Window width

The width of the windows including any frame (in m or ft).

Window height

The height of the windows including any frame (in m or ft).

Window spacing

The spacing between the each window on the façade (in m or ft). The window spacing is the centre to centre spacing between windows, not the gap between windows.

Sill height

This is the height of the base of the window from the base of the block (in m or ft).

Note 1: You can control the configuration of the building façades in greater detail by [drawing individual "custom" windows](#) at the surface level or by copying previously drawn windows at building level. In either of these cases glazing, vent and door façade layout model data is ignored.

Note 2: Flat roofs do not have default glazing set up using Roof glazing layout model data. To create openings on a flat roof you should go to the surface level and add them there.

Note 3: When the surface is **non-rectangular**, even with the 2 façade type options that prioritise Window to wall % (**3-Preferred height** and **1-Continuous horizontal**), the **Window to wall %** will not be perfectly maintained. For these surfaces, DesignBuilder calculates a rectangle that can accept the windows and starts from one end of the rectangle adding windows using the Window spacing data until no more fit into the rectangle. This results in an approximately correct looking façade but only prioritises **Window to wall %** in the rectangle, not accounting for the areas outside the bounding rectangle. For relatively large values of **Window spacing** on non-rectangular surfaces, no glazing may be generated. For example you may find that gable window surfaces have no default windows generated and it is often easiest to [draw a window](#) in this case.

Outside reveal depth

The **outside reveal depth** gives the extent to which the glazing is offset into the wall. As shown in the [diagram on the Frame and Dividers page](#) it is the distance from the exterior surface of the wall to the glazing outer surface (in m or ft).

Note: The **outside reveal depth** is used in EnergyPlus, Visualisations and Daylighting calculations and (unlike [Inside reveal depth](#)) is available regardless of whether the frame and dividers are included.

Note: EnergyPlus models outside reveals through the co-ordinates of the window, which are offset into the zone so the window and the base surface don't lie on the same plane. DesignBuilder provides window co-ordinates to EnergyPlus in this way and there is no specific data item in the IDF data to define it.

See also [Inside reveal depth](#).

EnergyPlus Window Dimensions - Technical Information

The **FenestrationSurface:Detailed** window data written to the EnergyPlus IDF input file will usually have a smaller area compared with the gross window area defined in DesignBuilder. EnergyPlus window sizes and positions are defined for the glazing area and the frame is extended from the window position to the parent wall/roof surface. DesignBuilder therefore accounts for the [frame](#) which is included in the window area defined in DesignBuilder but excluded from the EnergyPlus IDF window area. In cases where the frame option is switched off in DesignBuilder the frame area in the IDF data will exactly match the area set in DesignBuilder.

- "Glazing Assemblies" on page 420
- [Surface Polygons Generated for EnergyPlus - Technical Description](#)

Frame And Dividers

[Openings tab](#) in model data under **External Glazing, Internal Glazing and Roof Glazing** headers

If window frames and dividers are being modelled separately from the glazed part then the properties of the frame and dividers can be entered under the Frame and Dividers header on the Openings tab. A discussion on the methods that can be used for modelling windows and frames in "Glazing Assemblies" on page 420.

Important Note: Frames and dividers are only applied to *rectangular* windows (default and custom) and not to other shaped windows. They are also not applied when using the **Fill surface (100%)** facade type. If you are unsure about whether frames and dividers will be applied to a window you can use the [Visualisation rendered view](#) to check.

A frame surrounds the glazing in a rectangular window (schematics below). It is assumed that all frame characteristics, such as width, conductance and solar absorptance, are the same for the top, bottom and side elements of the frame. If the frame elements are not the same then you should enter area-weighted average values for the frame characteristics.

Has a Frame/Dividers

Check the **Has a Frame/Dividers** checkbox to enter details of the frame and/or dividers. In this case you can enter:

- The construction of the frame and dividers,
- The number of horizontal dividers and vertical dividers,
- Frame width and divider width (see diagrams below for definition).
- Inside reveal and sill details

[EnergyPlus window dimensions - technical information](#)

For **external windows on walls** the following dimensions in the direction of the glazing normal can also be entered:

- [Outside reveal depth](#)
- Inside reveal depth
- Inside sill depth
- Outside divider projection
- Inside divider projection
- Outside frame projection
- Inside frame projection
- Divider glass edge-centre conduction ratio
- Frame glass edge-centre conduction ratio
- Divider type

The definition of the above dimensions is shown in the diagrams.

Note: If the glazing does not have a frame or dividers or if the whole [glazing assembly](#) properties are being modelled directly using the **2-Simple** glazing [definition method](#) then you should uncheck the **Has a frame/dividers** box.

Reveal

Reveal surfaces are associated with the setback of the glazing from the outside/inside surfaces of the wall they are located in. If the depth and solar absorptance of these surfaces are specified, the program will calculate the reflection of beam solar radiation from these surfaces. The program also calculates the shadowing (onto the window) of beam and diffuse solar radiation by outside reveal surfaces.

The following fields specify the properties of the window reveal surfaces (reveals occur when the window is not in the same plane as the base surface). From this information and from the geometry of the window and the sun position, the program calculates beam solar radiation absorbed and reflected by the top, bottom, right and left sides of outside and inside window reveal surfaces. In doing this calculation, the shadowing on a reveal surface by other reveal surfaces is determined using the orientation of the reveal surfaces and the sun position.

It is assumed that:

- The window is an exterior window (EnergyPlus does not consider reveals for interior windows).
- The reveal surfaces are perpendicular to the window plane.
- If an exterior shade, screen or blind is in place it shades exterior and interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- If an interior shade or blind is in place it shades the interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- The possible shadowing on inside reveal surfaces by a window divider is ignored.
- The outside reveal surfaces (top, bottom, left, right) have the same solar absorptance and depth. This depth is not input here but is automatically determined by the program—from window and wall vertices—as the distance between the plane of the outside face of the glazing and plane of the outside face of the parent wall.
- The inside reveal surfaces are divided into two categories: (1) the bottom reveal surface, called here the "inside sill;" and (2) the other reveal surfaces (left, right and top).
- The left, right and top inside reveal surfaces have the same depth and solar absorptance. The inside sill is allowed to have depth and solar absorptance values that are different from the corresponding values for the other inside reveal surfaces.
- The inside sill depth is required to be greater than or equal to the depth of the other inside reveal surfaces. If the inside sill depth is greater than zero the depth of the other inside reveal surfaces is required to be greater than zero.
- The reflection of beam solar radiation from all reveal surfaces is assumed to be isotropic diffuse; there is no specular component.
- Half of the beam solar reflected from outside reveal surfaces is goes towards the window; the other half goes back to the exterior environment (i.e., reflection of this outward-going component from other outside reveal surfaces is not considered).
- The half that goes towards the window is added to the other solar radiation incident on the window. Correspondingly, half of the beam solar reflected from inside reveal surfaces goes towards the window, with the other half going into the zone. The portion going towards the window that is not reflected is absorbed in the glazing or is transmitted back out into the exterior environment.
- The beam solar that is absorbed by outside reveal surfaces is added to the solar absorbed by the outside surface of the window's parent wall; similarly, the beam solar absorbed by the inside reveal surfaces is added to the solar absorbed by the inside surface of the parent wall.
- The net effect of beam solar reflected from outside reveal surfaces is to increase the heat gain to the zone, whereas the effect of beam solar reflected from inside reveal surfaces is to decrease the heat gain to the zone since part of this reflected solar is transmitted back out the window.
- If the window has a frame, the absorption of reflected beam solar by the inside and outside surfaces of the frame is considered. The shadowing of the frame onto interior reveal surfaces is also considered.

The schematics below show how DesignBuilder reveal data is used to describe real glazing systems.

FAQ: Why does DesignBuilder require both Inside and Outside reveal depth data when wall thickness is available to calculate one reveal depth from the other?

Although it is possible for inside reveal depth to be calculated from the outside reveal depth and the [wall thickness](#), DesignBuilder allows both Inside and Outside reveal depths to be defined giving greater flexibility for situations where it is not possible to enter the wall thickness as accurately as one might like. For example the wall thickness may be entered as zero for simplified modelling. In such cases having direct control over the reveal depth data is an advantage.

Inside reveal depth

The **inside reveal depth** is the distance (in m or ft) from the innermost surface of the window to the interior wall surface as shown in the diagram above. This setting is used for EnergyPlus simulations but not for Visualisations and Radiance which use the [Outside reveal depth](#) to define the position of the window within the wall.

Note: **Inside reveal depth** data is provided to EnergyPlus in the same object as the frame and divider data, so when the [Has a frame/dividers](#) option is unchecked this data is not provided to EnergyPlus and the equivalent of a 0 inside reveal depth will be simulated.

See also [Outside reveal depth](#).

Inside sill depth

The **inside sill depth** is the distance (in m or ft) from the innermost surface of the window to the innermost end of the sill as shown in the diagram above.

Note: **Inside sill depth** data is provided to EnergyPlus in the same object as the frame and divider data, so when the [Has frame/dividers](#) option is unchecked this data is not provided to EnergyPlus and the equivalent of a 0 inside sill depth will be simulated.

Frame

Construction

Select the construction used to define the thermal properties of both the frame and dividers. In particular the frame construction is used to derive these EnergyPlus frame-related fields:

Frame conductance

The effective thermal conductance of the frame (in W/m²-K or Btu/h-ft²-F) measured from inside to outside frame surface *excluding surface air films* and taking frame and window geometry as associated 2-D conduction effects into account. Ideally the frame conductance should be obtained from THERM or some other 2-D calculation. DesignBuilder calculates the surface to surface conductance simply based on the material layers in the Frame construction. If you need to include particular 2-D conduction effects for the frame conductance then you should adjust the thickness or material properties of the layers of the frame construction.

Note: For metal frame windows DesignBuilder will calculate a very high surface to surface U-value for the frame construction, but the value that will be provided to EnergyPlus is limited to an maximum value of 500 W/m²k. This is in line with the limits used in the LBNL WINDOW program. This will have negligible difference on simulation as the corresponding thermal resistance is effectively zero in both cases (relative to the inside and outside film resistances).

Frame solar absorptance

The solar absorptance of the frame is derived from the surface properties of the *outermost* material layer. The value is assumed by EnergyPlus to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Frame visible absorptance

The visible absorptance of the frame is derived from the surface properties of the *outermost* material layer. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Frame thermal hemispherical emissivity

The thermal emissivity of the frame is derived from the surface properties of the *outermost* material layer and is assumed the same on the inside and outside.

Frame width

The width of the frame elements when projected onto the plane of the window (in m or ft). It is assumed that the top, bottom and side elements of the frame have the same width. If not, an average frame width should be entered such that the projected frame area calculated using the average value equals the sum of the areas of the frame elements.

Frame outside projection

The amount by which the frame projects outward from the outside surface of the window glazing (in m or ft). If the outer surface of the frame is flush with the glazing then enter 0. This value is used to calculate shadowing of frame onto glass, solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Frame inside projection

The amount by which the frame projects inward from the inside surface of the window glazing (in m or ft). If the inner surface of the frame is flush with the glazing then enter 0. This value is used to calculate solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Frame conductance

The effective thermal conductance of the frame measured from inside to outside frame surface (no air films) and taking 2-D conduction effects into account. Obtained from WINDOW or other 2-D calculation.

Frame glass edge centre conduction ratio

The glass conductance near the frame (excluding air films) divided by the glass conductance at the centre of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the frame and across the spacer that separates the glass panes. Values can be obtained from WINDOW for the user-selected glazing construction and frame characteristics.

Dividers

Dividers split the glazing up into separate lites. It is assumed that all divider elements have the same characteristics. If not, area-weighted average values should be used.

The schematic below show how DesignBuilder divider data is used to describe real glazing systems.

Divider type

The type of divider can be selected from these options:

- **1-Divided lite** means that the divider elements project out from the outside and inside surfaces of the glazing and divide the glazing into individual lites. For multi-pane glazing, this type of divider also has between-glass elements that separate the panes.

- **2-Suspended** is applicable only to multi-pane glazing. It means that the divider is suspended between the panes. (If there are more than two glass layers, the divider is assumed to be placed between the two outermost layers.)

Divider width

The width of the divider elements when projected onto the plane of the window (in m or ft). It is assumed that the horizontal and vertical divider elements have the same width. If not, an average divider width should be entered such that the projected divider area calculated using the average value equals the sum of the areas of the divider elements.

Horizontal dividers

The number of divider elements parallel to the top and bottom of the window.

Vertical dividers

The number of divider elements parallel to the sides of the window.

Divider outside projection

The amount by which the divider projects out from the outside surface of the window glazing (in m or ft). For Divider Type = Suspended, Divider Projection = 0.0. Used to calculate shadowing of divider onto glass, solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

Divider inside projection

The amount by which the divider projects inward from the inside surface of the window glazing (in m or ft). If the inner surface of the divider is flush with the glazing, enter 0.0. Used to calculate solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

Divider glass edge-centre conduction ratio

The glass conductance near the divider (excluding air films) divided by the glass conductance at the centre of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the divider and across the spacer that separates the glass panes. Values can be obtained from the WINDOW program for the user-selected glazing construction and divider characteristics.

Divider properties defined by the Frame construction

The [Construction](#) is used to define the thermal properties of both the frame and dividers. In particular the frame construction is used to derive these EnergyPlus divider-related fields:

Divider conductance

The effective thermal conductance of the divider (in W/m²-K or Btu/h-ft²-F) measured from inside to outside divider surface *excluding surface air films* and taking 2-D conduction effects into account. Obtained from the LBNL WINDOW program or other 2-D calculation. DesignBuilder calculates the surface to surface conductance simply based on the material layers. If you need to include particular 2-

D conduction effects for the frame/divider conductance then you should adjust the thickness or material properties of the layers of the frame construction.

Divider solar absorptance

The solar absorptance of the divider is derived from the surface properties of the *outermost* material layer. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Divider visible absorptance

The visible absorptance of the divider is derived from the surface properties of the *outermost* material layer. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Divider thermal hemispherical emissivity

The thermal emissivity of the divider, assumed to be the same on the inside and outside.

Note 1: If you do not wish to model the shading/reflection effect of the reveal/frame/divider then simply set the projection/depth to zero.

Note 2: In the case where a [window blind](#) is applied [mid-pane](#), any [dividers](#) that may have been specified for the window will not be applied in the model. EnergyPlus will generate a warning to this effect.

Glazing Assemblies

By default EnergyPlus models glazing and frames separately through separate window and frame objects. This topic discusses some of the issues related to modelling overall glazing assemblies including the glazed window and opaque frame elements.

There are two general ways to model glazing assemblies in DesignBuilder:

- **Data for glass and frame are entered separately** where "glass only" properties are defined in the [glazing](#) component selected and frame data is defined on the Openings tab under [Frame and Dividers](#). Note that when using this method EnergyPlus is not able to calculate an overall assembly U-value from separate window and frame data. If this output is required it can be done either approximately by adding the parallel conductance of the window and frame and taking the reciprocal or in more detail in a tool such as WINDOW.
- **Data for whole glazing assembly is entered directly**. This is done using the **2-Simple** glazing [definition method](#) and entering whole assembly U-value, solar and light transmission data in the [glazing](#) component selected on the Openings tab. In this case, to avoid double-counting the impact of the frame, it is important to remove the frame on the Openings tab for all windows using the whole assembly glazing system by unchecking the [Has frame/dividers](#) checkbox. If you only have access to "glass only" solar and visible transmission data then these can be multiplied by 1 minus the frame fraction to calculate the whole assembly solar and visible transmission values.

See the "Dimensions (Walls)" on page 410 topic for details on how glazing dimensions are written to EnergyPlus IDF.

Shading

[Openings tab](#) in model data under **External Glazing, Internal Glazing and Roof Glazing** headers

You can select two types of shading for external windows under the Shading header on the Openings tab:

- [Window shading](#) (blinds, curtains etc on wall and roof surfaces).
- [Local shading](#) (overhangs, louvres, sidefins on external wall surfaces only)

These types of shading can be used individually or combined.

Other shading mechanisms supported by DesignBuilder are:

- [Component blocks](#)
- Assemblies

Window and Local shading are both covered in the [Shading via louvres, overhangs, and side fins](#) tutorial

Window Shading

[Openings tab](#) in model data under **External Glazing, Internal Glazing and Roof Glazing** headers

Window shading can be included to reduce solar gains and increase resistance to heat conduction through windows. To include blinds, transparent insulation or electrochromic glazing check the **Window shading** checkbox. Then select the window blind component, the position of the shading device relative to the window and the way that the window shading is controlled.

Note: Window shading is not included in Heating design calculations.

Note: In [Radiance daylighting](#) calculations, Window shading is controlled using the [Annual Window shading](#) and [Point in time Window shading](#) settings on the Calculation options dialog. Depending on the setting selected, Window shading settings on the Openings tab may or may not be applied.

Note also that in Radiance, electrochromic and thermochromic glazing cannot dynamically respond to daylight levels. Instead, their performance is simulated using static properties based on the selected Glazing type. If Window shading is enabled and an electrochromic glass is selected, the daylighting simulation uses its darkest state.

Type

Select the [Window blind](#) component type. There are 5 categories of window blinds:

- [Slat](#) - slatted blinds whose transmission properties vary with solar position.
- [Shade](#) - assumed perfectly diffusing.
- [Electrochromic switchable](#) - if you select a blind of this category the Position (below) must be **4-Switchable**.
- [SageGlass electrochromic](#) - multi-state electrochromic glazing systems.
- [Transparent insulation](#) - Deprecated.

Position

The window shading devices can be positioned in one of four ways:

- **1-Inside** - the window shading devices is positioned inside the zone.
- **2-Mid-pane** - the window shading device is positioned between the inner pane and the second pane.
- **3-Outside** - the shading devices positioned outside.

- **4-Switchable** - select this option for [electrochromic glazing](#) in which case the outer pane is switched based on the shading control (below). This option is only available when a Window shading component whose category has been set to **Electrochromic switchable** has been selected as the Type (above).

Note: When selecting the **2-Mid-pane** position option you must ensure that there is sufficient gap between the innermost and second pane in the [Glazing](#) window gas layer to accommodate the blind [Slat width](#).

Control type

Control data specifies how the shading device is controlled. It determines whether the shading device is “on” or “off.” For [blinds and shades](#), when the device is “on” it is assumed to cover all of the window except its frame; when the device is “off” it is assumed to cover none of the window (whether “on” or “off” the shading device is assumed to cover none of the wall that the window is on). For [switchable glazing](#), “on” means that the glazing is in the fully-switched state and “off” means that it is in the unswitched state; for example, for electrochromic glazing, “on” means the glazing is in its darkest state and “off” means it is in its lightest state.

The choices for **Shading control type** are the following. *Equivalent EnergyPlus control types* are shown in italics. If a setpoint is applicable its units are shown in parentheses.

- **1-Always on** (*AlwaysOn*) - Shading devices are always activated.

The following six control types are used primarily to reduce zone cooling load due to window solar gain.

- **2-Daylight** (*MeetDaylightIlluminanceSetpoint*) - Used only with Position = **4-Switchable** in zones with [daylighting controls](#). In this case the transmittance of the glazing is adjusted to meet the [daylight illuminance set point](#) for the main photoelectric sensor used to control electric lighting according to daylight availability. This type of control assures that there is just enough daylight transmitted through windows with electrochromic shading to meet the daylighting requirements in a zone, and no more, thus reducing the cooling load. Note that the [daylight illuminance set point](#) is specified under [Environmental Control](#) on the Activity tab and that there is no option to apply separate setpoints for electrochromic shading and electric lighting control.
- **3-Schedule** - Shading operation is defined by a time only through a schedule. When the schedule has value 1 then shading operates, otherwise it does not.
- **4-Solar** (*OnIfHighSolarOnWindow*) - Shading is active if beam plus diffuse solar radiation incident on the window exceeds the [Solar setpoint](#).
- **5-Glare** (*OnIfHighGlare*) - Shading is on if the total daylight glare index at the zone’s first daylighting sensor from all of the exterior windows in the zone exceeds the maximum glare index specified in the daylighting input for zone.

Note: Glare control requires Lighting control to be switched on in the zone.

- **6-Outside air temp** (*OnIfHighOutsideAirTemp*) - Shading is on if outside air temperature exceeds [Outside air temperature setpoint](#).
- **7-Inside air temp** (*OnIfHighZoneAirTemp*) - Shading is on if zone air temperature in the previous time step exceeds the [Inside air temperature setpoint](#).
- **8-Cooling** (*OnIfHighZoneCooling*) - Shading is on if zone cooling rate in the previous time step is non-zero.

The following two control types can be used to reduce zone cooling load. They are applicable to any Shading type but are most appropriate for interior or exterior blinds, interior or exterior shades with low insulating value, or switchable glazing.

- **9-Day cooling and solar + night** (*OnNight/OnDayIfCoolingAndHighSolarOnWindow*) - Shading is on at night. Shading is on during the day when the solar radiation incident on the window exceeds the [Solar setpoint](#) and the zone cooling rate in the previous time step is non-zero.
- **10-Day cooling and solar** (*OffNight/OnDayIfCoolingAndHighSolarOnWindow*) - Shading is off at night. Shading is on during the day when the solar radiation incident on the window exceeds the [Solar setpoint](#) and if the zone cooling rate in the previous time step is non-zero.

The following three control types can be used to reduce zone heating load during the winter by reducing window conductive heat loss at night and leaving the window unshaded during the day to maximize solar gain. They are applicable to any Shading type but are most appropriate for interior or exterior shades with high insulating value ("movable insulation"). "Night" means the sun is down and "day" means the sun is up.

- **11-Night outside low air temp** (*OnNightIfLowOutsideTemp/OffDay*) - Shading is on at night if the outside air temperature is less than [Outside air temperature setpoint](#) and schedule, if specified, allows shading. Shading is off during the day.
- **12-Night inside low air temp** (*OnNightIfLowInsideTemp/OffDay*) - Shading is on at night if the zone air temperature in the previous time step is less than the [Inside air temperature setpoint](#) and schedule, if specified, allows shading. Shading is off during the day.
- **13-Night heating** (*OnNightIfHeating/OffDay*) - Shading is on at night if the zone heating rate in the previous time step is greater than zero and schedule, if specified, allows shading. Shading is off during the day.

The following two control types can be used to reduce zone heating and cooling load. They are applicable to any Shading type but are most appropriate for translucent interior or exterior shades with high insulating value ("translucent movable insulation").

- **14-Night outside low air temp + day cooling** (*OnNightIfLowOutsideTemp/OnDayIfCooling*) - Shading is on at night if the outside air temperature is less than the [Outside air temperature setpoint](#). Shading is on during the day if the zone cooling rate in the previous time step is non-zero.
- **15-Night heating + day cooling** (*OnNightIfHeating/OnDayIfCooling*) - Shading is on at night if the zone heating rate in the previous time step is non-zero. Shading is on during the day if the zone cooling rate in the previous time step is non-zero.
- **16-Horizontal solar** (*OnIfHighHorizontalSolar*) - Shading is on if total (beam plus diffuse) horizontal solar irradiance exceeds the [Solar setpoint](#) and schedule, if specified, allows shading.
- **17-Outdoor air temp + Solar on window** (*OnIfHighOutdoorAirTempAndHighSolarOnWindow*) - Shading is on if the outside air temperature exceeds the [Outside air temperature setpoint](#) and if the solar radiation incident on the window exceeds the [Solar setpoint](#).
- **18-Outdoor air temp + Horizontal solar** (*OnIfHighOutdoorAirTempAndHighHorizontalSolar*) - Shading is on if the outside air temperature exceeds the [Outside air temperature setpoint](#) and if the horizontal solar radiation on the window exceeds the [Solar setpoint](#).

Solar setpoint

The solar setpoint can be defined when one of these shading control types has been selected:

- **4-Solar**
- **9-Day cooling and solar + night**
- **10-Day cooling and solar**
- **16-Horizontal solar**
- **17-Outdoor air temp + Solar on window**
- **18-Outdoor air temp + Horizontal solar**

When the solar radiation (in W/m² or BTU/h-ft²) is higher than the setpoint entered here and any other required condition are met (control types 9, 10, 17 and 18) and the schedule allows shading operation then the window shading is activated.

Inside air temperature setpoint

The Inside air temperature setpoint can be defined when one of these shading control types has been selected:

- **7-Inside air temp**
- **12-Night inside low air temp**

For cooling control types, when the inside air temperature (in °C or °F) is *higher* than the setpoint entered here and the schedule allows shading operation, the window shading is activated. For heating control types the logic is reversed and shading is activated when the temperature is *below* this setpoint.

Outside air temperature setpoint

The Outside air temperature setpoint can be defined when one of these shading control types has been selected:

- **6-Outside air temp**
- **11-Night outside low air temp**
- **14-Night outside low air temp + day cooling**
- **17-Outdoor air temp + Solar on window**
- **18-Outdoor air temp + Horizontal solar**

When the outside air temperature (in °C or °F) is higher than the setpoint entered here and the schedule allows shading operation, the window shading is activated.

Slat Angle Control

Where a [Window shading](#) system from the **Slatted blinds** category is selected, the angle of the slats must be defined using the settings below.

Slat angle control type

The angle of the blind slats can be controlled using 3 options:

- **1-Fixed slat angle**, the default option where the angle of the slats is fixed to the [Slat angle](#) set on the Window shading dialog for the whole simulation.
- **2-Scheduled slat angle** where the angle of the slats is defined by a schedule selected on the **Slat angle schedule** below.
- **3-Block beam solar** where the slats are automatically orientated to be perpendicular to the direction of the sun's rays.

Slat angle schedule

The schedule defines the angle of the slats for every timestep in the simulation. This setting is only available when the **2-Scheduled slat angle** [Slat angle control type](#) is set. See Window shading dialog for the definition of [Slat angle](#).

Note: the operation of the blinds is controlled independently of the slat angle.

Operation

Operation schedule

For all shading control options apart from **Glare** and **Always on**, the shading can only be active when this schedule value is 1. Select the schedule **On** if the blind is always activated or if the only control is one of the others listed above.

Limitations

- If two daylight zones share an interior window, neither zone can have an exterior window whose shading device does glare control (i.e. [Control type](#) is **5-Glare**).
- If two daylight zones share an interior window, neither zone can have an exterior window with daylight control (i.e. [Control type](#) is **2-Daylight**).

Local Shading

[Openings tab](#) in model data under External Glazing headers

To include overhangs, sidefins and/or louvres check the **Local shading** checkbox. This shows the [Local shading component](#) data. DesignBuilder comes with a small database of Local shading devices, but if you cannot find a suitable component for your model, you can create a custom local shading component by clicking on the **Add new** button from the Selection dialog or from the info panel when using Learning mode.

Note: If you have repeated windows having same size, glazing type and window shading on a surface but different Local shading settings, you should switch off the [Lump similar windows on surface](#) model option. This is because the window lumping mechanism does not account for local shading and so windows may be lumped inappropriately in this case.

See also the [Shading via louvres, overhangs, and side fins](#) tutorials

Note: the DesignBuilder Local shading devices allow a range of different overhangs, side fins and louvres to be defined, but if you need to model a shading device not covered by the standard mechanism, you can draw custom shading devices using [Component blocks](#) or Assembly blocks.

Airflow Windows

[Openings tab](#) in model data under External Glazing header

Airflow windows can be modelled by checking the Airflow windows option on the Openings tab. This option can be used to specify the control mechanism for windows in which forced air flows in the gap between adjacent layers of glass. Such windows are called “airflow windows.” They are also known as “heat-extract windows” or “climate windows.”

A common application is to reduce the zone load by exhausting indoor air through the window. In the cooling season this picks up and expels some of the solar heat absorbed by the window glass (and by the between-glass shade or blind, if present). In the heating season this warms the window, reducing the heat loss from the window. A side benefit is increased thermal comfort. This is because the inside surface of the window will generally be cooler in summer and warmer in winter.

Limitations

- Windows must have two or three glass layers, i.e., double or triple-glazing. For triple-glazing the airflow is assumed to be between the two inner glass layers.
- An error will result if the gas in the airflow gap is other than air.
- If an airflow window has a between-glass shade or blind, the gas in the gap on either side of the shade or blind must be air.

The surface output variable **Surface Window Gap Convective Heat Transfer Rate** gives the heat picked up (or lost) by the gap airflow.

Gap airflow configurations for airflow windows:

- (a) **Air exhaust window:** Airflow Source = **1-Indoor air**, Airflow Destination = **2-Outdoor air**;
 (b) **Indoor air curtain window:** Airflow Source = **1-Indoor air**, Airflow Destination = **1-Indoor air**;
 (c) **Air supply window:** Airflow Source = **2-Outdoor air**, Airflow Destination = **1-Indoor air**;
 (d) **Outdoor air curtain window:** Airflow Source = **2-Outdoor air**, Airflow Destination = **2-Outdoor air**;
 (e) **Airflow to Return Air:** Airflow Source = **1-Indoor air**, Airflow Destination = **3-Return air**.

Based on "Active facades" Version no. 1, Belgian Building Research Institute, June 2002.

Note: Although Airflow control windows are defined under the **External Glazing** header (which normally holds data for wall glazing only) Airflow control window settings apply to *all* windows, including rooflights.

Airflow control

Check this option to include airflow control for external windows.

Airflow source

The source of the gap airflow. The choices are:

- **1-Indoor air** - Indoor air from the window's zone is passed through the window.
- **2-Outdoor air** - Outdoor air is passed through the window.

Airflow Destination

This is where the gap air goes after passing through the window. The choices are:

- **1-Indoor air** - the gap air goes to the indoor air of the window's zone.
- **2-Outdoor air** - the gap air goes to the outside air.
- **3-Return-air** - the gap air goes to the return air for the window's zone. This choice is allowed only if Airflow Source = 1-Indoor air. If the return air flow is zero, the gap air goes to the indoor air of the window's zone. If the sum of the gap airflow for all of the windows in a zone with **Airflow destination = 3-Return air** exceeds the return airflow, then the difference between this sum and the return airflow goes to the indoor air.

The diagram above shows the allowed combinations of **Airflow source** and **Airflow destination**. The allowed combinations of **Airflow source** and **Airflow destination** are:

- IndoorAir to OutdoorAir
- IndoorAir to IndoorAir
- IndoorAir to ReturnAir
- OutdoorAir to IndoorAir
- OutdoorAir to OutdoorAir

Maximum flow rate

The maximum value of the airflow (in m³/s per m of glazing width or ft³/min-ft). The value is typically 0.006 to 0.009 m³/s-m (4 to 6 ft³/min-ft). The airflow can be modulated through the Airflow multiplier schedule (below).

The fan energy used to move the air through the gap is generally very small and so is ignored.

Airflow multiplier schedule

The name of a [schedule](#) with values between 0.0 and 1.0. The timestep value of the airflow is **Maximum flow rate** times the schedule value.

Window Operation And Free Aperture

[Openings tab](#) in model data under **External Glazing**, **Internal Glazing** and **Roof Glazing** headers

Operation

The operation of windows can be defined by entering data under the **Operation** header. This data is only shown:

- When [Natural ventilation](#) is activated on the HVAC tab at the current level and Calculated natural ventilation is selected, or,
- For Internal glazing or both Calculated and Scheduled natural ventilation.

Schedule definition

Select the method to be used to define the timing of the window operation. Options are:

- **1-Follow occupancy** - the window can be opened when the zone is occupied and not when it is not occupied.
- **2-Custom schedule** - the operation of the window is controlled by a specific schedule which is displayed when this option is selected.

Operation schedule

When the **Schedule definition** method (above) has been set to **2-Custom schedule** the schedule to be used to define window opening times can be selected. It defaults to the occupancy schedule based on the most recently loaded [Activity template](#).

Control option (internal windows only)

The control option allows you to define how *internal windows* behave in natural ventilation systems and whether they operate purely based on a schedule or, when using Calculated natural ventilation, whether they are linked to the main natural ventilation controllers defined on the HVAC tab. This data is not available for external windows. The options are:

For **Calculated** natural ventilation:

- **1-Constant** - the size of the internal window airflow opening (when open) is constant and the opening of internal windows is controlled entirely by schedule, i.e. it is not affected by any of the natural ventilation controls on the HVAC tab. In particular the [Internal control mode](#) setting on the HVAC tab is not used.
- **2-Use Internal control mode** - the internal windows are controlled using natural ventilation [Internal control mode](#) settings on the HVAC tab in combination with the operation schedule described below.

Note: When using Calculated natural ventilation and the **1-Constant** control option is selected, airflow through internal windows will occur (when enabled by the operation schedule) regardless of whether natural ventilation is [activated](#) on the HVAC tab. The **2-Use Internal control mode** option should only be selected when natural ventilation has been [activated](#) on the HVAC tab.

For **Scheduled** natural ventilation:

- **1-Control by schedule** - the internal windows are controlled entirely by schedule and are not affected by any of the natural ventilation controls on the HVAC tab.
- **2-Closed** - the internal windows are always closed and do not allow any airflow to be exchanged.

Note: When using Scheduled natural ventilation and the **1-Control by schedule** control option is selected, airflow through internal windows will occur (when enabled by the operation schedule) regardless of whether natural ventilation is [activated](#) on the HVAC tab.

Operation schedule

The schedule that specifies when window venting is available. A zero or negative schedule value means window venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by natural ventilation [Control Mode](#)) are satisfied.

Note: Fractional availability schedules do not restrict the venting in any way. When the schedule value > 0 the window can open, when it is 0 the window is closed.

An exception to this rule is for [CIBSE TM59:2026](#) simulations when using the [Restrict venting factor by schedule](#) option which, when set, does allow time-varying window aperture restriction to be defined through this schedule.

This schedule allows you to turn off venting at certain times of the day (at night, for example), of the week (on weekends, for example), or of the year (during the winter, for example).

If used with natural ventilation [Control Mode](#) = **4-Constant**, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero. If Ventilation Control Mode = **1-NoVent**, this schedule has no effect.

The windows are 'open' when:

$T_{\text{zone_air}} > T_{\text{setpoint}}$ AND $T_{\text{zone_air}} > T_{\text{outside_air}}$ AND the schedule value = 1

The ventilation rate is calculated based on the pressure difference across the opening calculated from wind and stack pressure effects using equations described in [Natural Ventilation Modelling](#).

Free Aperture

The size and position of window opening airflow paths can be defined by entering data under the **Free Aperture** header. This data is used in both:

- a. EnergyPlus Calculated natural ventilation Airflow network simulations and
- b. CFD simulations

Note: While free aperture data is shown when the Scheduled natural ventilation model option is selected, this data is not used in EnergyPlus simulations. In this case the data is only made available to allow it to be used for CFD boundary conditions.

Opening position

The position of the opening in the window can be selected from

- **1-Top** - the aperture is in the top of the window. Air flow in and out will flow through the top of the window.
- **2-Bottom** - the aperture is in the bottom of the window. Air flow in and out will flow through the bottom of the window.
- **3-Right** - the aperture is in the right of the window (looking from outside). Air flow in and out will flow through the right of the window.
- **4-Left** - the aperture is in the left of the window (looking from outside). Air flow in and out will flow through the left of the window.

Windows should be rectangular to have an airflow opening in them and the position of the opening on the window can be defined by selecting from the above list. Options **3-Right** and **4-Left** will give identical simulation results as the EnergyPlus Airflow Network only accounts for the z-position of openings. The difference is useful for CFD simulations though.

Note: Non-rectangular windows (or rotated rectangular windows) can still be used as airflow openings. In this case for Airflow Network opening size purposes, EnergyPlus treats triangular windows as if they were rectangular with height and width based on the maximum dimensions in each direction.

% Glazing area opens

The % Glazing area opens data allows you to define the openable window "free area" as a percentage of the window area. For example enter 20 if the window free area is 20% of the total glazed window area. In simple terms this is the fraction of the window that can be opened, but it should also take into account the effect of any obstructions and in practice a more correct definition for the free area is the "cross-sectional (measurable, geometric) area".

The "free area" is multiplied by the [discharge coefficient](#) to give the "effective area" for the Airflow Network calculations within EnergyPlus.

Note: When calculating the **% Glazing area opens** you should divide the openable window free area by the total glazed area of the window, excluding the frame. The expandable section below under [Opening Areas For Fully Opening Windows with Frames](#) provides advice on how to deal with fully opening windows with large frames to avoid under-representing airflow.

Tip: A good rule of thumb to approximate of the free area for a top hung window is the bottom rectangular "opening area" plus 2 x the triangular side opening area. For closely spaced windows the side triangles

should be reduced to account for the reduced effective opening area. A similar calculation can be made for side and bottom hung windows.

A couple of good reference for how to measure or otherwise obtain this data are:

- [A review of ventilation opening area terminology](#) by, Benjamin M. Jones, Malcolm J. Cook, Shaun D. Fitzgerald, Christopher R. Iddon., 2015.
- "Air of Credibility" in the CIBSE Journal May 2016 (same authors as above).

Note: if [modulation](#) is switched on (it isn't by default) the glazing opening areas defined here are multiplied by a factor to account for external conditions in EnergyPlus Airflow Network simulations when using Calculated natural ventilation.

Tip: In some cases it is best to switch off the [Lump similar windows on surface](#) model option when using Calculated natural ventilation. Particular cases where this is important are a) when there are windows of the same size and type but different **% Glazing area opens** values on the same surface and b) where the air flow rate through individual windows is required, e.g. when preparing boundary conditions for a linked EnergyPlus CFD study.

Opening Areas For Fully Opening Windows with Frames

Because EnergyPlus only uses the glazed area for window airflow calculations, for windows with significant frames that fully open, a correction needs to be applied to avoid under-representing the airflow in the simulation.

Considering the example in the image above, when drawing a glazed opening such as a window or patio door, the opening height and width are entered including the frame. The width of the frame, which includes any fixed parts (black) and opening parts (red) is entered as a single frame width figure and DesignBuilder subtracts this to give the glazed area.

However, because only the glazed area is used for airflow calculations, the airflow through the opening would be under-represented if we simply entered **% Glazing area opens** to be 100% without further correction. The wider the frame, the bigger the issue. For example, a typical uPVC glazed door might have a frame width of 0.14m, of which 0.04m is the fixed frame (black) and 0.1m is part of the opening area (red) along with the glazing. For a 2.1m high by 0.9m wide glazed door, the free area opening size when fully

open (subtracting the black fixed frame area) would be 1.66 m², which is 1.47 times the glazed only area in blue (1.13 m²) used in the airflow network ventilation calculations.

This issue can have significant implications for airflow modelling in some overheating assessments. It is not possible to correct for it by increasing the glazed area (either by increasing the opening size or reducing the frame size) because that would affect solar gains.

In our example case of the large glazed door, with 100% openable area there is no scope to increase the **% Glazing area opens** beyond 100%. **The recommended workaround is to modify the [discharge coefficient](#) to account for the missing frame area in the airflow model.** In our example, multiplying the default discharge coefficient for the window (0.65) by 1.47 (actual ventilation free area divided by glazed only area) gives a discharge coefficient of 0.95 which can be entered to compensate for the under representation of opening size.

Credit: Stephen Porritt for this workaround and the image.

Internal Window operation in CFD

Like other internal openings, internal windows cannot have airflow specified to define air movement in CFD simulations. Because CFD is for a snapshot in time and so does not use schedules, if you have loaded simulation results for a time where an internal window was closed *due to the schedule or some control setting*, to ensure that you see the same behaviour in CFD you can set the **% Glazing area opens** to zero to zero in a copy of the simulation model.

Discharge coefficient

The constant discharge coefficient for the window (C_d) is used for Calculated natural ventilation only. The value must be between 0.0 and 1.0. Separate values can be entered for internal, external and roof windows.

For open doors and holes, a discharge coefficient can be entered on the Advanced tab of the model options dialog under the [Natural Ventilation](#) header.

Theory explaining the discharge coefficient

From the IEA Annex 20 document [Air flow Through Large Openings in Buildings](#).

The EnergyPlus Airflow Network model is based on the following empirical powerlaw relationship between the flow and the pressure difference across a crack or opening in the building envelope:

$$Q = C(\Delta P)^n$$

The volumetric flow rate, Q [m³/s], is a simple function of the pressure drop, ΔP [Pa], across the opening. A common variation of the powerlaw equation is:

$$F = C(\Delta P)^n$$

where the mass flow rate, F [kg/s], is a simple function of the pressure drop. A third variation is related to the orifice equation:

$$Q = C_d A \sqrt{\frac{2\Delta P}{\rho}}$$

where:

C_d = discharge coefficient, and
 A = orifice opening area.

Theoretically, the value of the flow exponent, n , should lie between 0.5 and 1.0. Large openings are characterized by values very close to 0.5, while values near 0.65 have been found for small crack-like openings.

Suggested values for discharge coefficient

The literature suggests a large range of different values for discharge coefficient (symbol C_d often used in orifice equations). For example IEA Annexe 20 Air flow Through Large Openings in Buildings indicates that discharge coefficients reported in the literature vary between 0.3 and 0.8 and that it is not understood what causes the differences.

Other sources recommend a value close to 0.6. For example the [CONTAMW 2.0 User Manual](#) states that the *discharge coefficient, is related to the dynamic effects and is typically close to 0.6 for an orifice and slightly higher for other openings in buildings.*

ASHRAE propose the following correlation based on interzone temperature differences:

$$C_d = 0.4 + 0.0045 \delta T$$

for the range δT 0.5 to 40.

Given other uncertainties in natural ventilation calculations (wind pressure coefficients, effective areas of real-world openings and crack flows etc), using a discharge coefficient between 0.60 and 0.65 should provide sufficient accuracy.

Scheduled Natural Ventilation

Airflow through individual *external* windows, vents, doors and holes are not modelled explicitly with [Scheduled](#) natural ventilation because the natural ventilation airflow from outside is defined using the total [natural ventilation flow rate](#) and [operation](#) on the [HVAC](#) tab. *No operation data or free aperture needs to be entered on the Openings tab for external windows in this case.*

Note: Natural Ventilation can be [overridden to be off](#) on the HVAC tab for both Calculated and Scheduled model options.

Internal Glazing

[Openings tab](#) in model data

The data under the Internal Glazing header applies to all glazing lying on internal partition walls. You can enter information on:

- [Dimensions](#)
- [Frame](#)
- [Operation](#)

The data is as described previously for [External glazing](#) except that [shading](#) is not permitted for internal glazing.

Note: Data for internal windows is not available at zone level as explained in "Zone Level Data for Internal Surfaces" on page 700.

Roof Glazing

[Openings tab](#) in model data

The data under the Roof Glazing header applies to all glazing lying on external roof surfaces. You can enter information on:

- [Dimensions](#)
- [Frame](#)
- [Shading](#)
- [Operation](#)

Note: flat roofs do not have default glazing set up using Roof glazing layout model data. To create openings on a flat roof you should go to the surface level and add them there.

Dimensions (Roofs)

[Openings tab](#) in model data under Sloped Roof Windows / Skylights headers

Notes: The settings for roof window dimensions are similar to those for external walls with some important exceptions:

- The façade settings apply only to *sloping* roofs. **Flat roofs are not covered by this data.** To create windows in flat roofs you should draw them at surface level or clone them at building level from other façades. The reason flat roofs do not use the façade mechanism is that there is no top and bottom to set up sills, height vs width etc.
- Only the **0-None**, **4-Fixed width and height** and **5-Fill surface (100%)** façade options are available. There is therefore no way to set up windows using a % glazing (WWR) on roof surfaces.
- Reveals are not provided for roof surfaces.

Facade types

There are 3 façade types available for sloped roof surfaces:

- **0-None** - there is no glazing.
- **4-Fixed width and height** - windows have fixed width and height.
- **5-Fill surface (100%)** - the entire surface is filled with glazing and there is **no frame**.

Window width

The width of the windows including any frame (in m or ft).

Window height

The height of the windows including any frame (in m or ft).

Window spacing

The spacing between the each window on the façade (in m or ft). The window spacing is the centre to centre spacing between windows, not the gap between windows.

Sill height

This is the height of the base of the window from the base of the block (in m or ft).

Frame And Dividers

[Openings tab](#) in model data under **External Glazing, Internal Glazing and Roof Glazing** headers

If window frames and dividers are being modelled separately from the glazed part then the properties of the frame and dividers can be entered under the Frame and Dividers header on the Openings tab. A discussion on the methods that can be used for modelling windows and frames in "Glazing Assemblies" on page 420.

Important Note: Frames and dividers are only applied to *rectangular* windows (default and custom) and not to other shaped windows. They are also not applied when using the **Fill surface (100%)** facade type. If you are unsure about whether frames and dividers will be applied to a window you can use the [Visualisation rendered view](#) to check.

A frame surrounds the glazing in a rectangular window (schematics below). It is assumed that all frame characteristics, such as width, conductance and solar absorptance, are the same for the top, bottom and side elements of the frame. If the frame elements are not the same then you should enter area-weighted average values for the frame characteristics.

Has a Frame/Dividers

Check the **Has a Frame/Dividers** checkbox to enter details of the frame and/or dividers. In this case you can enter:

- The construction of the frame and dividers,
- The number of horizontal dividers and vertical dividers,
- Frame width and divider width (see diagrams below for definition).
- Inside reveal and sill details

[EnergyPlus window dimensions - technical information](#)

For **external windows on walls** the following dimensions in the direction of the glazing normal can also be entered:

- [Outside reveal depth](#)
- Inside reveal depth
- Inside sill depth
- Outside divider projection
- Inside divider projection
- Outside frame projection
- Inside frame projection
- Divider glass edge-centre conduction ratio
- Frame glass edge-centre conduction ratio
- Divider type

The definition of the above dimensions is shown in the diagrams.

Note: If the glazing does not have a frame or dividers or if the whole [glazing assembly](#) properties are being modelled directly using the **2-Simple** glazing [definition method](#) then you should uncheck the **Has a frame/dividers** box.

Reveal

Reveal surfaces are associated with the setback of the glazing from the outside/inside surfaces of the wall they are located in. If the depth and solar absorptance of these surfaces are specified, the program will calculate the reflection of beam solar radiation from these surfaces. The program also calculates the shadowing (onto the window) of beam and diffuse solar radiation by outside reveal surfaces.

The following fields specify the properties of the window reveal surfaces (reveals occur when the window is not in the same plane as the base surface). From this information and from the geometry of the window and the sun position, the program calculates beam solar radiation absorbed and reflected by the top, bottom, right and left sides of outside and inside window reveal surfaces. In doing this calculation, the shadowing on a

reveal surface by other reveal surfaces is determined using the orientation of the reveal surfaces and the sun position.

It is assumed that:

- The window is an exterior window (EnergyPlus does not consider reveals for interior windows).
- The reveal surfaces are perpendicular to the window plane.
- If an exterior shade, screen or blind is in place it shades exterior and interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- If an interior shade or blind is in place it shades the interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- The possible shadowing on inside reveal surfaces by a window divider is ignored.
- The outside reveal surfaces (top, bottom, left, right) have the same solar absorptance and depth. This depth is not input here but is automatically determined by the program—from window and wall vertices—as the distance between the plane of the outside face of the glazing and plane of the outside face of the parent wall.
- The inside reveal surfaces are divided into two categories: (1) the bottom reveal surface, called here the "inside sill;" and (2) the other reveal surfaces (left, right and top).
- The left, right and top inside reveal surfaces have the same depth and solar absorptance. The inside sill is allowed to have depth and solar absorptance values that are different from the corresponding values for the other inside reveal surfaces.
- The inside sill depth is required to be greater than or equal to the depth of the other inside reveal surfaces. If the inside sill depth is greater than zero the depth of the other inside reveal surfaces is required to be greater than zero.
- The reflection of beam solar radiation from all reveal surfaces is assumed to be isotropic diffuse; there is no specular component.
- Half of the beam solar reflected from outside reveal surfaces is goes towards the window; the other half goes back to the exterior environment (i.e., reflection of this outward-going component from other outside reveal surfaces is not considered).
- The half that goes towards the window is added to the other solar radiation incident on the window. Correspondingly, half of the beam solar reflected from inside reveal surfaces goes towards the window, with the other half going into the zone. The portion going towards the window that is not reflected is absorbed in the glazing or is transmitted back out into the exterior environment.
- The beam solar that is absorbed by outside reveal surfaces is added to the solar absorbed by the outside surface of the window's parent wall; similarly, the beam solar absorbed by the inside reveal surfaces is added to the solar absorbed by the inside surface of the parent wall.
- The net effect of beam solar reflected from outside reveal surfaces is to increase the heat gain to the zone, whereas the effect of beam solar reflected from inside reveal surfaces is to decrease the heat gain to the zone since part of this reflected solar is transmitted back out the window.
- If the window has a frame, the absorption of reflected beam solar by the inside and outside surfaces of the frame is considered. The shadowing of the frame onto interior reveal surfaces is also considered.

The schematics below show how DesignBuilder reveal data is used to describe real glazing systems.

FAQ: Why does DesignBuilder require both Inside and Outside reveal depth data when wall thickness is available to calculate one reveal depth from the other?

Although it is possible for inside reveal depth to be calculated from the outside reveal depth and the [wall thickness](#), DesignBuilder allows both Inside and Outside reveal depths to be defined giving greater flexibility for situations where it is not possible to enter the wall thickness as accurately as one might like. For example the wall thickness may be entered as zero for simplified modelling. In such cases having direct control over the reveal depth data is an advantage.

Inside reveal depth

The **inside reveal depth** is the distance (in m or ft) from the innermost surface of the window to the interior wall surface as shown in the diagram above. This setting is used for EnergyPlus simulations but not for Visualisations and Radiance which use the [Outside reveal depth](#) to define the position of the window within the wall.

Note: **Inside reveal depth** data is provided to EnergyPlus in the same object as the frame and divider data, so when the [Has a frame/dividers](#) option is unchecked this data is not provided to EnergyPlus and the equivalent of a 0 inside reveal depth will be simulated.

See also [Outside reveal depth](#).

Inside sill depth

The **inside sill depth** is the distance (in m or ft) from the innermost surface of the window to the innermost end of the sill as shown in the diagram above.

Note: **Inside sill depth** data is provided to EnergyPlus in the same object as the frame and divider data, so when the [Has frame/dividers](#) option is unchecked this data is not provided to EnergyPlus and the equivalent of a 0 inside sill depth will be simulated.

Frame

Construction

Select the construction used to define the thermal properties of both the frame and dividers. In particular the frame construction is used to derive these EnergyPlus frame-related fields:

Frame conductance

The effective thermal conductance of the frame (in W/m²-K or Btu/h-ft²-F) measured from inside to outside frame surface *excluding surface air films* and taking frame and window geometry as associated 2-D conduction effects into account. Ideally the frame conductance should be obtained from THERM or some other 2-D calculation. DesignBuilder calculates the surface to surface conductance simply based on the material layers in the Frame construction. If you need to include particular 2-D conduction effects for the frame conductance then you should adjust the thickness or material properties of the layers of the frame construction.

Note: For metal frame windows DesignBuilder will calculate a very high surface to surface U-value for the frame construction, but the value that will be provided to EnergyPlus is limited to an maximum value of 500 W/m²k. This is in line with the limits used in the LBNL WINDOW program. This will have negligible difference on simulation as the corresponding thermal resistance is effectively zero in both cases (relative to the inside and outside film resistances).

Frame solar absorptance

The solar absorptance of the frame is derived from the surface properties of the *outermost* material layer. The value is assumed by EnergyPlus to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Frame visible absorptance

The visible absorptance of the frame is derived from the surface properties of the *outermost* material layer. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Frame thermal hemispherical emissivity

The thermal emissivity of the frame is derived from the surface properties of the *outermost* material layer and is assumed the same on the inside and outside.

Frame width

The width of the frame elements when projected onto the plane of the window (in m or ft). It is assumed that the top, bottom and side elements of the frame have the same width. If not, an average frame width should be entered such that the projected frame area calculated using the average value equals the sum of the areas of the frame elements.

Frame outside projection

The amount by which the frame projects outward from the outside surface of the window glazing (in m or ft). If the outer surface of the frame is flush with the glazing then enter 0. This value is used to calculate shadowing of frame onto glass, solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Frame inside projection

The amount by which the frame projects inward from the inside surface of the window glazing (in m or ft). If the inner surface of the frame is flush with the glazing then enter 0. This value is used to calculate solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Frame conductance

The effective thermal conductance of the frame measured from inside to outside frame surface (no air films) and taking 2-D conduction effects into account. Obtained from WINDOW or other 2-D calculation.

Frame glass edge centre conduction ratio

The glass conductance near the frame (excluding air films) divided by the glass conductance at the centre of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the frame and across the spacer that separates the glass panes. Values can be obtained from WINDOW for the user-selected glazing construction and frame characteristics.

Dividers

Dividers split the glazing up into separate lites. It is assumed that all divider elements have the same characteristics. If not, area-weighted average values should be used.

The schematic below show how DesignBuilder divider data is used to describe real glazing systems.

Divider type

The type of divider can be selected from these options:

- **1-Divided lite** means that the divider elements project out from the outside and inside surfaces of the glazing and divide the glazing into individual lites. For multi-pane glazing, this type of divider also has between-glass elements that separate the panes.

- **2-Suspended** is applicable only to multi-pane glazing. It means that the divider is suspended between the panes. (If there are more than two glass layers, the divider is assumed to be placed between the two outermost layers.)

Divider width

The width of the divider elements when projected onto the plane of the window (in m or ft). It is assumed that the horizontal and vertical divider elements have the same width. If not, an average divider width should be entered such that the projected divider area calculated using the average value equals the sum of the areas of the divider elements.

Horizontal dividers

The number of divider elements parallel to the top and bottom of the window.

Vertical dividers

The number of divider elements parallel to the sides of the window.

Divider outside projection

The amount by which the divider projects out from the outside surface of the window glazing (in m or ft). For Divider Type = Suspended, Divider Projection = 0.0. Used to calculate shadowing of divider onto glass, solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

Divider inside projection

The amount by which the divider projects inward from the inside surface of the window glazing (in m or ft). If the inner surface of the divider is flush with the glazing, enter 0.0. Used to calculate solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

Divider glass edge-centre conduction ratio

The glass conductance near the divider (excluding air films) divided by the glass conductance at the centre of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the divider and across the spacer that separates the glass panes. Values can be obtained from the WINDOW program for the user-selected glazing construction and divider characteristics.

Divider properties defined by the Frame construction

The [Construction](#) is used to define the thermal properties of both the frame and dividers. In particular the frame construction is used to derive these EnergyPlus divider-related fields:

Divider conductance

The effective thermal conductance of the divider (in W/m²-K or Btu/h-ft²-F) measured from inside to outside divider surface *excluding surface air films* and taking 2-D conduction effects into account. Obtained from the LBNL WINDOW program or other 2-D calculation. DesignBuilder calculates the surface to surface conductance simply based on the material layers. If you need to include particular 2-

D conduction effects for the frame/divider conductance then you should adjust the thickness or material properties of the layers of the frame construction.

Divider solar absorptance

The solar absorptance of the divider is derived from the surface properties of the *outermost* material layer. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Divider visible absorptance

The visible absorptance of the divider is derived from the surface properties of the *outermost* material layer. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

Divider thermal hemispherical emissivity

The thermal emissivity of the divider, assumed to be the same on the inside and outside.

Note 1: If you do not wish to model the shading/reflection effect of the reveal/frame/divider then simply set the projection/depth to zero.

Note 2: In the case where a [window blind](#) is applied [mid-pane](#), any [dividers](#) that may have been specified for the window will not be applied in the model. EnergyPlus will generate a warning to this effect.

Roof Shading

[Openings tab](#) in model data under Roof Glazing headers

You can select one type of shading for external roof windows:

- [Window shading](#) (blinds, curtains etc walls and roofs).

Local shading is not available for roof windows.

Window Shading

[Openings tab](#) in model data under External Glazing, Internal Glazing and Roof Glazing headers

Window shading can be included to reduce solar gains and increase resistance to heat conduction through windows. To include blinds, transparent insulation or electrochromic glazing check the **Window shading** checkbox. Then select the window blind component, the position of the shading device relative to the window and the way that the window shading is controlled.

Note: Window shading is not included in Heating design calculations.

Note: In [Radiance daylighting](#) calculations, Window shading is controlled using the [Annual Window shading](#) and [Point in time Window shading](#) settings on the Calculation options dialog. Depending on the setting selected, Window shading settings on the Openings tab may or may not be applied.

Note also that in Radiance, electrochromic and thermochromic glazing cannot dynamically respond to

daylight levels. Instead, their performance is simulated using static properties based on the selected Glazing type. If Window shading is enabled and an electrochromic glass is selected, the daylighting simulation uses its darkest state.

Type

Select the [Window blind](#) component type. There are 5 categories of window blinds:

- [Slat](#) - slatted blinds whose transmission properties vary with solar position.
- [Shade](#) - assumed perfectly diffusing.
- [Electrochromic switchable](#) - if you select a blind of this category the Position (below) must be **4-Switchable**.
- [SageGlass electrochromic](#) - multi-state electrochromic glazing systems.
- [Transparent insulation](#) - Deprecated.

Position

The window shading devices can be positioned in one of four ways:

- **1-Inside** - the window shading device is positioned inside the zone.
- **2-Mid-pane** - the window shading device is positioned between the inner pane and the second pane.
- **3-Outside** - the shading device is positioned outside.
- **4-Switchable** - select this option for [electrochromic glazing](#) in which case the outer pane is switched based on the shading control (below). This option is only available when a Window shading component whose category has been set to **Electrochromic switchable** has been selected as the Type (above).

Note: When selecting the **2-Mid-pane** position option you must ensure that there is sufficient gap between the innermost and second pane in the [Glazing](#) window gas layer to accommodate the blind [Slat width](#).

Control type

Control data specifies how the shading device is controlled. It determines whether the shading device is “on” or “off.” For [blinds and shades](#), when the device is “on” it is assumed to cover all of the window except its frame; when the device is “off” it is assumed to cover none of the window (whether “on” or “off” the shading device is assumed to cover none of the wall that the window is on). For [switchable glazing](#), “on” means that the glazing is in the fully-switched state and “off” means that it is in the unswitched state; for example, for electrochromic glazing, “on” means the glazing is in its darkest state and “off” means it is in its lightest state.

The choices for **Shading control type** are the following. *Equivalent EnergyPlus control types* are shown in italics. If a setpoint is applicable its units are shown in parentheses.

- **1-Always on** (*AlwaysOn*) - Shading devices are always activated.

The following six control types are used primarily to reduce zone cooling load due to window solar gain.

- **2-Daylight** (*MeetDaylightIlluminanceSetpoint*) - Used only with Position = **4-Switchable** in zones with [daylighting controls](#). In this case the transmittance of the glazing is adjusted to meet the [daylight illuminance set point](#) for the main photoelectric sensor used to control electric lighting according to daylight availability. This type of control assures that there is just enough daylight transmitted through windows with electrochromic shading to meet the daylighting requirements in a zone, and no more, thus reducing the cooling load. Note that the [daylight illuminance set point](#) is specified under [Environmental Control](#) on the Activity tab and that there is no option to apply separate setpoints for electrochromic shading and electric lighting control.
- **3-Schedule** - Shading operation is defined by a time only through a schedule. When the schedule has value 1 then shading operates, otherwise it does not.
- **4-Solar** (*OnIfHighSolarOnWindow*) - Shading is active if beam plus diffuse solar radiation incident on the window exceeds the [Solar setpoint](#).
- **5-Glare** (*OnIfHighGlare*) - Shading is on if the total daylight glare index at the zone's first daylighting sensor from all of the exterior windows in the zone exceeds the maximum glare index specified in the daylighting input for zone.

Note: Glare control requires Lighting control to be switched on in the zone.

- **6-Outside air temp** (*OnIfHighOutsideAirTemp*) - Shading is on if outside air temperature exceeds [Outside air temperature setpoint](#).
- **7-Inside air temp** (*OnIfHighZoneAirTemp*) - Shading is on if zone air temperature in the previous time step exceeds the [Inside air temperature setpoint](#).
- **8-Cooling** (*OnIfHighZoneCooling*) - Shading is on if zone cooling rate in the previous time step is non-zero.

The following two control types can be used to reduce zone cooling load. They are applicable to any Shading type but are most appropriate for interior or exterior blinds, interior or exterior shades with low insulating value, or switchable glazing.

- **9-Day cooling and solar + night** (*OnNight/OnDayIfCoolingAndHighSolarOnWindow*) - Shading is on at night. Shading is on during the day when the solar radiation incident on the window exceeds the [Solar setpoint](#) and the zone cooling rate in the previous time step is non-zero.
- **10-Day cooling and solar** (*OffNight/OnDayIfCoolingAndHighSolarOnWindow*) - Shading is off at night. Shading is on during the day when the solar radiation incident on the window exceeds the [Solar setpoint](#) and if the zone cooling rate in the previous time step is non-zero.

The following three control types can be used to reduce zone heating load during the winter by reducing window conductive heat loss at night and leaving the window unshaded during the day to maximize solar gain. They are applicable to any Shading type but are most appropriate for interior or exterior shades with high insulating value ("movable insulation"). "Night" means the sun is down and "day" means the sun is up.

- **11-Night outside low air temp** (*OnNightIfLowOutsideTemp/OffDay*) - Shading is on at night if the outside air temperature is less than [Outside air temperature setpoint](#) and schedule, if specified, allows shading. Shading is off during the day.
- **12-Night inside low air temp** (*OnNightIfLowInsideTemp/OffDay*) - Shading is on at night if the zone air temperature in the previous time step is less than the [Inside air temperature setpoint](#) and schedule, if specified, allows shading. Shading is off during the day.
- **13-Night heating** (*OnNightIfHeating/OffDay*) - Shading is on at night if the zone heating rate in the previous time step is greater than zero and schedule, if specified, allows shading. Shading is off during the day.

The following two control types can be used to reduce zone heating and cooling load. They are applicable to any Shading type but are most appropriate for translucent interior or exterior shades with high insulating value ("translucent movable insulation").

- **14-Night outside low air temp + day cooling** (*OnNightIfLowOutsideTemp/OnDayIfCooling*) - Shading is on at night if the outside air temperature is less than the [Outside air temperature setpoint](#). Shading is on during the day if the zone cooling rate in the previous time step is non-zero.
- **15-Night heating + day cooling** (*OnNightIfHeating/OnDayIfCooling*) - Shading is on at night if the zone heating rate in the previous time step is non-zero. Shading is on during the day if the zone cooling rate in the previous time step is non-zero.
- **16-Horizontal solar** (*OnIfHighHorizontalSolar*) - Shading is on if total (beam plus diffuse) horizontal solar irradiance exceeds the [Solar setpoint](#) and schedule, if specified, allows shading.
- **17-Outdoor air temp + Solar on window** (*OnIfHighOutdoorAirTempAndHighSolarOnWindow*) - Shading is on if the outside air temperature exceeds the [Outside air temperature setpoint](#) and if the solar radiation incident on the window exceeds the [Solar setpoint](#).
- **18-Outdoor air temp + Horizontal solar** (*OnIfHighOutdoorAirTempAndHighHorizontalSolar*) - Shading is on if the outside air temperature exceeds the [Outside air temperature setpoint](#) and if the horizontal solar radiation on the window exceeds the [Solar setpoint](#).

Solar setpoint

The solar setpoint can be defined when one of these shading control types has been selected:

- **4-Solar**
- **9-Day cooling and solar + night**
- **10-Day cooling and solar**
- **16-Horizontal solar**
- **17-Outdoor air temp + Solar on window**
- **18-Outdoor air temp + Horizontal solar**

When the solar radiation (in W/m² or BTU/h-ft²) is higher than the setpoint entered here and any other required condition are met (control types 9, 10, 17 and 18) and the schedule allows shading operation then the window shading is activated.

Inside air temperature setpoint

The Inside air temperature setpoint can be defined when one of these shading control types has been selected:

- **7-Inside air temp**
- **12-Night inside low air temp**

For cooling control types, when the inside air temperature (in °C or °F) is *higher* than the setpoint entered here and the schedule allows shading operation, the window shading is activated. For heating control types the logic is reversed and shading is activated when the temperature is *below* this setpoint.

Outside air temperature setpoint

The Outside air temperature setpoint can be defined when one of these shading control types has been selected:

- **6-Outside air temp**
- **11-Night outside low air temp**
- **14-Night outside low air temp + day cooling**
- **17-Outdoor air temp + Solar on window**
- **18-Outdoor air temp + Horizontal solar**

When the outside air temperature (in °C or °F) is higher than the setpoint entered here and the schedule allows shading operation, the window shading is activated.

Slat Angle Control

Where a [Window shading](#) system from the **Slatted blinds** category is selected, the angle of the slats must be defined using the settings below.

Slat angle control type

The angle of the blind slats can be controlled using 3 options:

- **1-Fixed slat angle**, the default option where the angle of the slats is fixed to the [Slat angle](#) set on the Window shading dialog for the whole simulation.
- **2-Scheduled slat angle** where the angle of the slats is defined by a schedule selected on the **Slat angle schedule** below.
- **3-Block beam solar** where the slats are automatically orientated to be perpendicular to the direction of the sun's rays.

Slat angle schedule

The schedule defines the angle of the slats for every timestep in the simulation. This setting is only available when the **2-Scheduled slat angle** [Slat angle control type](#) is set. See Window shading dialog for the definition of [Slat angle](#).

Note: the operation of the blinds is controlled independently of the slat angle.

Operation

Operation schedule

For all shading control options apart from **Glare** and **Always on**, the shading can only be active when this schedule value is 1. Select the schedule **On** if the blind is always activated or if the only control is one of the others listed above.

Limitations

- If two daylight zones share an interior window, neither zone can have an exterior window whose shading device does glare control (i.e. [Control type](#) is **5-Glare**).
- If two daylight zones share an interior window, neither zone can have an exterior window with daylight control (i.e. [Control type](#) is **2-Daylight**).

Window Operation And Free Aperture

[Openings tab](#) in model data under **External Glazing**, **Internal Glazing** and **Roof Glazing** headers

Operation

The operation of windows can be defined by entering data under the **Operation** header. This data is only shown:

- When [Natural ventilation](#) is activated on the HVAC tab at the current level and Calculated natural ventilation is selected, or,
- For Internal glazing or both Calculated and Scheduled natural ventilation.

Schedule definition

Select the method to be used to define the timing of the window operation. Options are:

- **1-Follow occupancy** - the window can be opened when the zone is occupied and not when it is not occupied.
- **2-Custom schedule** - the operation of the window is controlled by a specific schedule which is displayed when this option is selected.

Operation schedule

When the **Schedule definition** method (above) has been set to **2-Custom schedule** the schedule to be used to define window opening times can be selected. It defaults to the occupancy schedule based on the most recently loaded [Activity template](#).

Control option (internal windows only)

The control option allows you to define how *internal windows* behave in natural ventilation systems and whether they operate purely based on a schedule or, when using Calculated natural ventilation, whether they are linked to the main natural ventilation controllers defined on the HVAC tab. This data is not available for external windows. The options are:

For **Calculated** natural ventilation:

- **1-Constant** - the size of the internal window airflow opening (when open) is constant and the opening of internal windows is controlled entirely by schedule, i.e. it is not affected by any of the natural ventilation controls on the HVAC tab. In particular the [Internal control mode](#) setting on the HVAC tab is not used.
- **2-Use Internal control mode** - the internal windows are controlled using natural ventilation [Internal control mode](#) settings on the HVAC tab in combination with the operation schedule described below.

Note: When using Calculated natural ventilation and the **1-Constant** control option is selected, airflow through internal windows will occur (when enabled by the operation schedule) regardless of whether natural ventilation is [activated](#) on the HVAC tab. The **2-Use Internal control mode** option should only be selected when natural ventilation has been [activated](#) on the HVAC tab.

For **Scheduled** natural ventilation:

- **1-Control by schedule** - the internal windows are controlled entirely by schedule and are not affected by any of the natural ventilation controls on the HVAC tab.
- **2-Closed** - the internal windows are always closed and do not allow any airflow to be exchanged.

Note: When using Scheduled natural ventilation and the **1-Control by schedule** control option is selected, airflow through internal windows will occur (when enabled by the operation schedule) regardless of whether natural ventilation is [activated](#) on the HVAC tab.

Operation schedule

The schedule that specifies when window venting is available. A zero or negative schedule value means window venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by natural ventilation [Control Mode](#)) are satisfied.

Note: Fractional availability schedules do not restrict the venting in any way. When the schedule value > 0 the window can open, when it is 0 the window is closed.

An exception to this rule is for [CIBSE TM59:2026](#) simulations when using the [Restrict venting factor by schedule](#) option which, when set, does allow time-varying window aperture restriction to be defined through this schedule.

This schedule allows you to turn off venting at certain times of the day (at night, for example), of the week (on weekends, for example), or of the year (during the winter, for example).

If used with natural ventilation [Control Mode](#) = **4-Constant**, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero. If Ventilation Control Mode = **1-NoVent**, this schedule has no effect.

The windows are 'open' when:

$T_{\text{zone_air}} > T_{\text{setpoint}}$ AND $T_{\text{zone_air}} > T_{\text{outside_air}}$ AND the schedule value = 1

The ventilation rate is calculated based on the pressure difference across the opening calculated from wind and stack pressure effects using equations described in [Natural Ventilation Modelling](#).

Free Aperture

The size and position of window opening airflow paths can be defined by entering data under the **Free Aperture** header. This data is used in both:

- a. EnergyPlus Calculated natural ventilation Airflow network simulations and
- b. CFD simulations

Note: While free aperture data is shown when the Scheduled natural ventilation model option is selected, this data is not used in EnergyPlus simulations. In this case the data is only made available to allow it to be used for CFD boundary conditions.

Opening position

The position of the opening in the window can be selected from

- **1-Top** - the aperture is in the top of the window. Air flow in and out will flow through the top of the window.
- **2-Bottom** - the aperture is in the bottom of the window. Air flow in and out will flow through the bottom of the window.
- **3-Right** - the aperture is in the right of the window (looking from outside). Air flow in and out will flow through the right of the window.
- **4-Left** - the aperture is in the left of the window (looking from outside). Air flow in and out will flow through the left of the window.

Windows should be rectangular to have an airflow opening in them and the position of the opening on the window can be defined by selecting from the above list. Options **3-Right** and **4-Left** will give identical simulation results as the EnergyPlus Airflow Network only accounts for the z-position of openings. The difference is useful for CFD simulations though.

Note: Non-rectangular windows (or rotated rectangular windows) can still be used as airflow openings. In this case for Airflow Network opening size purposes, EnergyPlus treats triangular windows as if they were rectangular with height and width based on the maximum dimensions in each direction.

% Glazing area opens

The % Glazing area opens data allows you to define the openable window "free area" as a percentage of the window area. For example enter 20 if the window free area is 20% of the total glazed window area. In simple terms this is the fraction of the window that can be opened, but it should also take into account the effect of any obstructions and in practice a more correct definition for the free area is the "cross-sectional (measurable, geometric) area".

The "free area" is multiplied by the [discharge coefficient](#) to give the "effective area" for the Airflow Network calculations within EnergyPlus.

Note: When calculating the **% Glazing area opens** you should divide the openable window free area by the total glazed area of the window, excluding the frame. The expandable section below under [Opening Areas For Fully Opening Windows with Frames](#) provides advice on how to deal with fully opening windows with large frames to avoid under-representing airflow.

Tip: A good rule of thumb to approximate of the free area for a top hung window is the bottom rectangular "opening area" plus 2 x the triangular side opening area. For closely spaced windows the side triangles should be reduced to account for the reduced effective opening area. A similar calculation can be made for side and bottom hung windows.

A couple of good reference for how to measure or otherwise obtain this data are:

- [A review of ventilation opening area terminology](#) by, Benjamin M. Jones, Malcolm J. Cook, Shaun D. Fitzgerald, Christopher R. Iddon., 2015.
- "Air of Credibility" in the CIBSE Journal May 2016 (same authors as above).

Note: if [modulation](#) is switched on (it isn't by default) the glazing opening areas defined here are multiplied by a factor to account for external conditions in EnergyPlus Airflow Network simulations when using Calculated natural ventilation.

Tip: In some cases it is best to switch off the [Lump similar windows on surface](#) model option when using Calculated natural ventilation. Particular cases where this is important are a) when there are windows of the same size and type but different **% Glazing area opens** values on the same surface and b) where the air flow rate through individual windows is required, e.g. when preparing boundary conditions for a linked EnergyPlus CFD study.

Opening Areas For Fully Opening Windows with Frames

Because EnergyPlus only uses the glazed area for window airflow calculations, for windows with significant frames that fully open, a correction needs to be applied to avoid under-representing the airflow in the simulation.

Considering the example in the image above, when drawing a glazed opening such as a window or patio door, the opening height and width are entered including the frame. The width of the frame, which includes any fixed parts (black) and opening parts (red) is entered as a single frame width figure and DesignBuilder subtracts this to give the glazed area.

However, because only the glazed area is used for airflow calculations, the airflow through the opening would be under-represented if we simply entered **% Glazing area opens** to be 100% without further correction. The wider the frame, the bigger the issue. For example, a typical uPVC glazed door might have a frame width of 0.14m, of which 0.04m is the fixed frame (black) and 0.1m is part of the opening area (red) along with the glazing. For a 2.1m high by 0.9m wide glazed door, the free area opening size when fully open (subtracting the black fixed frame area) would be 1.66 m², which is 1.47 times the glazed only area in blue (1.13 m²) used in the airflow network ventilation calculations.

This issue can have significant implications for airflow modelling in some overheating assessments. It is not possible to correct for it by increasing the glazed area (either by increasing the opening size or reducing the frame size) because that would affect solar gains.

In our example case of the large glazed door, with 100% openable area there is no scope to increase the **% Glazing area opens** beyond 100%. **The recommended workaround is to modify the discharge coefficient to account for the missing frame area in the airflow model.** In our example, multiplying the default discharge coefficient for the window (0.65) by 1.47 (actual ventilation free area divided by glazed only area) gives a discharge coefficient of 0.95 which can be entered to compensate for the under representation of opening size.

Credit: Stephen Porritt for this workaround and the image.

Internal Window operation in CFD

Like other internal openings, internal windows cannot have airflow specified to define air movement in CFD simulations. Because CFD is for a snapshot in time and so does not use schedules, if you have loaded simulation results for a time where an internal window was closed *due to the schedule or some control setting*, to ensure that you see the same behaviour in CFD you can set the **% Glazing area opens** to zero in a copy of the simulation model.

Discharge coefficient

The constant discharge coefficient for the window (C_d) is used for Calculated natural ventilation only. The value must be between 0.0 and 1.0. Separate values can be entered for internal, external and roof windows.

For open doors and holes, a discharge coefficient can be entered on the Advanced tab of the model options dialog under the [Natural Ventilation](#) header.

Theory explaining the discharge coefficient

From the IEA Annexe 20 document [Air flow Through Large Openings in Buildings](#).

The EnergyPlus Airflow Network model is based on the following empirical powerlaw relationship between the flow and the pressure difference across a crack or opening in the building envelope:

$$Q = C(\Delta P)^n$$

The volumetric flow rate, Q [m³/s], is a simple function of the pressure drop, ΔP [Pa], across the opening. A common variation of the powerlaw equation is:

$$F = C(\Delta P)^n$$

where the mass flow rate, F [kg/s], is a simple function of the pressure drop. A third variation is related to the orifice equation:

$$Q = C_d A \sqrt{\frac{2\Delta P}{\rho}}$$

where:

C_d = discharge coefficient, and
 A = orifice opening area.

Theoretically, the value of the flow exponent, n , should lie between 0.5 and 1.0. Large openings are characterized by values very close to 0.5, while values near 0.65 have been found for small crack-like openings.

Suggested values for discharge coefficient

The literature suggests a large range of different values for discharge coefficient (symbol C_d often used in orifice equations). For example IEA Annexe 20 Air flow Through Large Openings in Buildings indicates that discharge coefficients reported in the literature vary between 0.3 and 0.8 and that it is not understood what causes the differences.

Other sources recommend a value close to 0.6. For example the [CONTAMW 2.0 User Manual](#) states that the *discharge coefficient, is related to the dynamic effects and is typically close to 0.6 for an orifice and slightly higher for other openings in buildings.*

ASHRAE propose the following correlation based on interzone temperature differences:

$$C_d = 0.4 + 0.0045 \delta T$$

for the range δT 0.5 to 40.

Given other uncertainties in natural ventilation calculations (wind pressure coefficients, effective areas of real-world openings and crack flows etc), using a discharge coefficient between 0.60 and 0.65 should provide sufficient accuracy.

Scheduled Natural Ventilation

Airflow through individual *external* windows, vents, doors and holes are not modelled explicitly with [Scheduled natural ventilation](#) because the natural ventilation airflow from outside is defined using the total [natural ventilation flow rate](#) and [operation](#) on the [HVAC](#) tab. *No operation data or free aperture needs to be entered on the Openings tab for external windows in this case.*

Note: Natural Ventilation can be [overridden to be off](#) on the HVAC tab for both Calculated and Scheduled model options.

Doors

[Openings tab](#) in model data

External Doors

External doors are used for modelling heat conduction. They can also provide airflow between the exterior and interior when the [Calculated natural ventilation](#) model option is selected.

Doors can be added to the model by navigating to the appropriate surface and either:

- Setting the **Auto generate** option and settings the Preferred width and height options. In this case, for surfaces that do not contain any custom openings, a single door will be positioned at the left side of the surface looking from outside.
- Alternatively, for more control over the placement position of the doors, you can draw the doors using the [Draw Door](#) command. Note that on surfaces where custom openings have been defined, any changes to door layout model data on the [Opening tab](#) is ignored.

Note: if you have drawn custom doors at the surface level then these will be used even if the **Auto generate** checkbox is not checked. The **Auto generate** checkbox only controls the automatic generation of doors, not their use in the calculations.

The additional door model data that can be added is described under:

- [Door Placement](#) - defines the size and position of door when using the Auto generate option.
- [Door Operation](#) - defines the times when doors can open.

Important Note: The external door operation settings are only made available for editing when the [Natural Ventilation > On](#) checkbox is checked on the HVAC tab.

Glazed doors

Doors use opaque constructions and if the door you wish to model is transparent then it should be modelled using a window. If only a portion of the door is glazed then the door could be modelled as part door and part window.

Internal Doors

Regardless of the Natural ventilation model option selected, data on internal doors can always be accessed. In this case the properties of the selected door component(s) define the resistance to heat conduction and airflow (see details below under **Door Modelling**).

Note: Internal door data is not available at zone level to avoid ambiguity when different settings are made in adjacent zones. Surface level internal door settings are generally inherited from block level, however settings for *inter-block* doors are inherited from the building level. For details on these rules see: "Zone Level Data for Internal Surfaces" on page 700.

Otherwise the same comments made above for External doors also apply to Internal doors.

Door Modelling

Calculated Natural Ventilation (Simulations only)

Each door is modelled using:

- An EnergyPlus **Door**. The heat conduction through the **Door** component is combined with the Wall and Partition results.
- An EnergyPlus **AirflowNetwork:MultiZone:Component:DetailedOpening** and other associated AirflowNetwork components, providing a flow path. You can define Door operation.

Scheduled Natural Ventilation (and Heating and Cooling Design Calculations)

Each door is modelled using:

- An EnergyPlus **Door**. The heat conduction through the **Door** component is combined with the Wall and Partition results.
- Outdoor air ventilation airflows are defined explicitly for zones as a whole and external doors do not contribute to this.
- Internal doors also have an EnergyPlus **ZoneMixing** object using [parameters](#) set in the [Model options](#) dialog. External doors do not exchange air with Scheduled natural ventilation.

More details on how door operation is modelled in the [Door Operation](#) help topic.

Door Placement

[Openings tab in model data under Doors](#)

On surfaces where no custom openings have been defined, you can create doors simply by checking the 'Doors fitted?' options under the External and Internal Doors headers. In this case a single door is positioned on each surface in place of one of the windows in the automatically generated facade layout.

Door Operation

[Openings tab in model data under Doors](#)

The operation of doors can be defined by entering data under Operation headers:

- **% Area door opens** - defines the area of the door which opens relative to the total area to give an approximation of the actual opening size and,
- **% Time door is open** - defines the average time the door is in the open position. Accounts for the fact that during occupied periods the door may open and close repeatedly.
- **Opening position** - defines where in the door the airflow opening is located. Select from:
 - 1-Top,
 - 2-Bottom,
 - 3-Right and
 - 4-Left

The way this data is used depends on the Natural ventilation model option set, but in both cases the concept of doors opening and closing can be approximated by reducing the size of the door opening area to account for the fact that the door is closed for much of the time.

Note: the same **Opening position** and **% Area door opens** data is used for both EnergyPlus Calculated natural ventilation and CFD calculations. **% Time door is open** is not used in CFD.

Internal Door operation in CFD

Like other internal openings, internal doors cannot have airflow specified to define air movement in CFD simulations. Because CFD is for a snapshot in time and so does not use schedules, if you have loaded simulation results for a time where an internal door was closed *due to the schedule setting*, to ensure that you see the same behaviour in CFD you can set the **% Area door opens** to zero in a copy of the simulation model.

Calculated Natural Ventilation

The door opening size used in the simulation is calculated by multiplying the **% Area door opens** by the **% Time the door is open** by the gross door area. The position of the opening within the door is defined by the opening position. The ventilation rate through the door opening is calculated at each time step based on the wind + stack pressure difference across the opening at the time.

Operation schedule

The Operation schedule is used to control timing of the door opening. Note that the schedule should have values of 0 and 1 only and intermediate fractional values do not indicate partial opening.

Scheduled Natural Ventilation

External door opening is not modelled explicitly with the Scheduled natural ventilation model data setting. Instead, the total natural ventilation flow rate and operation is defined for each zone on the [HVAC tab](#). No operation data is entered on the Openings tab for external doors.

Internal doors - when [parameters](#) set in the [Model options](#) enable it, airflow through doors is modelling using the EnergyPlus **ZoneMixing** object which mixes air between the two adjacent zones. DesignBuilder uses an approximate empirical relationship to calculate the mixing flow:

$$\text{Flow (m3/s)} = \text{Door area (m2)} * \% \text{ area door opens} * \% \text{ time door is open} * \\ \text{FAirflowRatePerOpeningArea}$$

where *FAirflowRatePerOpeningArea* is a factor used to obtain the mixing flow from the opening area. The [value of this factor](#) can be defined on the Model options dialog on the Advanced tab under Natural ventilation. The default value is 0.1 m3/s-m2.

A schedule can be applied to control timing of the mixing flow.

Note: The [Airflow through internal openings](#) model option must be checked to obtain airflow through internal doors when using Scheduled natural ventilation.

Operation schedule

The Operation schedule is used to control timing of the mixing flow. Note that the schedule should have values of 0 and 1 only and intermediate fractional values do not indicate partial opening.

Note: For both Scheduled and Calculated natural ventilation options, door opening is controlled entirely by schedule and is not affected by natural ventilation controls.

Vents And Holes

[Openings tab](#) in model data

External Vents

External vents are typically used for modelling airflow through external vent openings for the purposes of providing fresh air and/or zone cooling. They are only used when the [Calculated natural ventilation](#) model option is selected. When using [Scheduled natural ventilation](#) external vents should, in general, not be added to the model since, in this case, outdoor airflow is defined explicitly at zone level and the vent settings cannot be accessed to define the conductance and texture.

Vents can be added to the model by navigating to the appropriate surface and either:

- Setting the **Auto generate** option and settings the Preferred width and height options. In this case a vent will be positioned under each of the windows (if the vent spacing is the same as the window spacing), or,
- Alternatively, for more control over the placement position of the vents, you can draw the vents using the [Draw vent](#) command. Note that on surfaces where custom openings have been defined, any changes to vent layout model data on the [Opening tab](#) is ignored.

Note: if you have drawn custom vents at the surface level then these will be used even if the **Auto generate** checkbox is not checked. The **Auto generate** checkbox only controls the automatic generation of vents, not their use in the calculations.

Vent type

The [properties of the vent](#) are defined by the selection of the vent type:

Select the [vent component](#) that holds additional property data on the vent type such as the construction, texture and discharge coefficient to be applied.

The additional vent model data that can be added is described under:

- [Vent Placement](#) - defines the size and position of vents when using the Auto generate option.
- [Vent Operation](#) - defines the times when vents can operate.

Important Note: The external vent operation settings are only made available for editing when the [Natural Ventilation > On](#) checkbox is checked on the HVAC tab.

Roof Vents

Roof vents are defined as any vents placed on an external pitched or flat roof surface. The vent type for roofs is defined separately under the **Roof** header.

Although roof vents have a separate vent type selection you should use the same operation schedule as for External vents to define simulated vent opening availability. This data can be accessed under the Vents > External > Operation header.

Internal Vents

Regardless of the Natural ventilation model option selected, data on internal vents can always be accessed. In this case the properties of the selected vent component(s) define the resistance to heat conduction and airflow (see details below under [Vent Modelling](#)).

Note: Internal vent data is not available at zone level to avoid ambiguity when different settings are made in adjacent zones. Surface level internal vent settings are generally inherited from block level, however settings for *inter-block* vents are inherited from the building level. For details on these rules see: "Zone Level Data for Internal Surfaces" on page 700.

Otherwise the same comments made above for External vents also apply to Internal vents.

Vent Modelling

Calculated Natural Ventilation (Simulations only)

Each vent is modelled using:

- An EnergyPlus [Door](#). The heat conduction through the vent [Door](#) component is combined with the Wall and Partition results.
- An EnergyPlus [AirflowNetwork:MultiZone:Component:DetailedOpening](#) and other associated AirflowNetwork components, providing a controllable flow path. You can define [Vent operation](#).

Scheduled Natural Ventilation (and Heating and Cooling Design Calculations)

Each vent is modelled using:

- An EnergyPlus [Door](#). The heat conduction through the vent [Door](#) component is combined with the Wall and Partition results.
- Outdoor air ventilation airflows are defined explicitly for zones as a whole and external vents do not contribute to this.
- Internal vents also have an EnergyPlus [ZoneMixing](#) object using [parameters](#) set in the [Model options](#) dialog. External vents do not exchange air explicitly with Scheduled natural ventilation.

Holes

[Holes](#) are modelled in a similar way to vents with some exceptions:

- Holes must be drawn at surface level.
- Airflow through holes is uncontrolled, i.e. the airflow path is active all the time.
- Drawing holes can be used as a way to [merge](#) two zones when the [Merge zones connected by holes](#) Model option is set.
- Holes are used internally with DesignBuilder to model the heat transfer and airflow through [Virtual partitions](#).
- The [discharge coefficient to be used for all holes](#) (and doors) in the model is defined on the Advanced tab of the Model options dialog under the Natural Ventilation header. The default discharge coefficient is 0.65 is used. For vents the [vent component](#) defines the discharge coefficient.

Hole Modelling

Calculated Natural Ventilation (Simulations only)

Each hole is modelled using an EnergyPlus sub-surface and an airflow connection:

- Sub-surface:
 - When using the [1-Minimum shadowing](#) or [2-Full exterior](#) solar distribution Model options external holes are modelled using 'perfectly clear' windows which transmit all solar radiation and visible light, while internal holes are modelled using EnergyPlus Doors and an [Infrared Transparent](#) construction.

- When using [3-Full interior and exterior](#) solar distribution, all holes are represented using 'perfectly clear' windows which transmit all solar radiation and visible light. In this case heat conduction through window components are displayed in results as **Internal Natural vent** and **External Natural vent** as appropriate.
- EnergyPlus **AirflowNetwork:MultiZone:Component:DetailedOpening** and other associated AirflowNetwork components, providing a non-controllable flow path.

Scheduled Natural Ventilation (and Heating and Cooling Design Calculations)

Each hole is modelled using an EnergyPlus sub-surface as follows:

- External holes are represented using 'perfectly clear' windows which transmit all solar radiation and visible light. In this case the heat conduction through windows is displayed in results as **External Natural vent**. External holes do not exchange air explicitly with Scheduled natural ventilation.
- Internal holes are modelled using an internal "door" between the 2 zones and, if the [Airflow through internal openings](#) Model option is selected, an EnergyPlus **ZoneMixing** object is also included using [parameters](#) set in the Model options dialog.

Vent Placement

[Openings tab in model data under Vents](#)

On surfaces where no custom openings have been defined, you can create vents simply by checking the **Auto generate** options under the External and Internal Vents headers. In this case vents are positioned on each surface using **Vent spacing** and **Vent height above floor** in the automatically generated facade layout. Typically, a single vent is positioned under each of the windows (if the vent spacing is entered to be the same as the window spacing).

Note: When using the **Auto generate** option, please be aware that, as for windows, vents can only be automatically generated for walls and sloping roofs. Auto generation isn't possible on horizontal surfaces such as flat roofs.

Note: It is often more convenient to place vents manually by drawing them at surface level or by copying previously drawn vents at building level.

Vent area

Enter the area of the area of each vent (in m2 or ft2).

Vent spacing

The spacing between the each vent on the facade (in m or ft). In many cases this will be the same as the [window spacing](#) if auto generated windows are also being used. The **vent spacing** is the centre-to-centre spacing between vents, not the gap between vents.

Vent height above floor

The height of the vent centre above the zone floor level (in m or ft).

Vent Operation

[Openings tab in model data under Vents](#)

The operation of vents can be defined by entering timing data under **Operation** headers.

Control option (internal vents only)

The control option allows you to define how *internal vents* behave in natural ventilation systems and whether they operate purely based on a schedule or, when using Calculated natural ventilation, whether they are linked to the main natural ventilation controllers defined on the HVAC tab. This settings is not available for external vents. The options are:

For **Calculated** natural ventilation:

- **1-Constant** - the size of the internal vent airflow opening (when open) is constant and the opening of internal vents is controlled entirely by schedule, i.e. it is not affected by any of the natural ventilation controls on the HVAC tab. In particular the [Internal control mode](#) setting on the HVAC tab is not used.
- **2-Use Internal control mode** - the internal vents are controlled using natural ventilation [Internal control mode](#) settings on the HVAC tab in combination with the operation schedule described below.

For **Scheduled** natural ventilation:

- **1-Control by schedule** - the internal vents are controlled entirely by schedule and are not affected by any of the natural ventilation controls on the HVAC tab.
- **2-Closed** - the internal vents are always closed and do not allow any airflow to be exchanged.

The way this data is used depends on the Natural ventilation model option set:

Calculated Natural Ventilation

The ventilation rate through the vent is calculated based on the wind and stack pressure calculated at each time step in the simulation.

Operation schedule

The Operation schedule is used to control timing of the vent opening availability. Note that the schedule should have values of 0 and 1 only and intermediate fractional values do not indicate partial opening.

Note: Vents on a roof surface use the operation schedule under the Vents > External > Operation header to define simulated vent opening availability.

Scheduled Natural Ventilation

External vent opening is not modelled explicitly with the Scheduled natural ventilation model data setting. Instead, the total natural ventilation flow rate and operation is defined for each zone on the [HVAC tab](#). *No operation data is entered on the Openings tab for external vents.*

Internal vents are modelled using the EnergyPlus **ZoneMixing** object which mixes air between the two adjacent zones. DesignBuilder uses an approximate empirical relationship to calculate the mixing flow:

$$\text{Flow (m3/s)} = \text{Door area (m2)} * \% \text{ area door opens} * \% \text{ time door is open} * \text{FAirflowRatePerOpeningArea}$$

where *FAirflowRatePerOpeningArea* is a factor used to obtain the mixing flow from the opening area. The [value of this factor](#) can be defined on the Model options dialog on the Advanced tab under Natural ventilation. The default value is 0.1 m3/s-m2.

A schedule can be applied to control timing of the mixing flow.

Note: The [Airflow through internal openings](#) model option must be checked to obtain airflow through internal vents when using Scheduled natural ventilation.

Operation schedule

The Operation schedule is used to control timing of the mixing flow. Note that the schedule should have values of 0 and 1 only and intermediate fractional values do not indicate partial opening.

Wind Pressure Coefficients

[Openings tab in model data](#)

You can enter [Wind pressure coefficients](#) (WPC) for wind incidence angles in 45° increments for each surface in the model. DesignBuilder automatically sets up default WPC data as surfaces are created using published [Wind Pressure Coefficient template data](#).

Wind pressure coefficients are only available when using the Calculated natural ventilation model option.

Note: the wind incidence angles are relative to the surface normal for each surface.

Lighting Model Data

[Lighting tab in model data](#)

Templates

You can load generic Lighting data by clicking on the Template option under Lighting Template and then by clicking on the '...' at the right of the line.

When you make a selection from the list of [Lighting templates](#), data from selected template will be loaded to the model.

With [Early gains](#), the lighting gains in the space are separated into Task and General lighting.

You can also open these headers to enter lighting details where they are different from those loaded from the template:

- [General Lighting](#)
- [Task Lighting](#)
- [Lighting Control](#)
- [Exterior Lighting](#)
- "Lighting Cost" on page 469

When you load lighting data from template, the actual general lighting internal gain is calculated by dividing the W/m²/100 lux data in the template by the required [illuminance level](#) as set on the [Activity tab](#). Consequently you should make sure the correct activity data has been loaded in each zone before loading lighting templates. Also, you may need to explicitly load data in each zone by checking each zone in the Target tab of the 'Load data from template' dialog.

Lighting data generates simulation data at the **Zone level**.

See also the [Lighting data and daylight controls](#) tutorial

General Lighting

[Lighting tab in model data](#)

General lighting accounts for the main lighting in the room. It is assumed to be able to be replaced by daylight through lighting control.

Units

When the [Gain definition level](#) model option is set to **2-Zone by zone in model data** you can select the units to be used for lighting here on the Lighting tab. Choose from the options:

- **1-Power density** - where the General lighting gains are defined per floor area. This method has the advantage that the level of gains can clearly be understood by looking at W/m² or W/ft² values and floor area. However it can cause problems when loading data from lighting templates in that if the activity is changed subsequently with a different illuminance requirement, the lighting power density is not updated. This issue has led to the introduction of the second option.
- **2-Normalised power density** - Although the units for Normalised power density (W/m²-100 lux or W/ft²-fc) may seem quite obscure, this method of defining lighting gains has advantages over using simple Power density. Namely that the actual lighting level is associated with the lighting system type without the need to refer to the zone activity and hence illuminance requirement. So if a particular lighting system type is installed throughout a building, but the building has a range of activities each with different illuminance requirements, it will usually be possible to enter the lighting **Normalised power density** value once only at building level, set the activity for each zone and obtain realistic lighting gains.
- **3-Absolute zone power** - where the lighting gains are defined as W without reference to the zone floor area. This option is used when the actual absolute lighting gains levels are known in W. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Note: When using the **3-Absolute zone power** option, the lighting gains data is normally entered individually for each zone because values inherited from building and block levels will typically not be correct.

Gain

Set the design level of energy consumption due to general lighting. Depending on the [Lighting gain units](#) model option setting, the gains data is entered as **Power density** (in W/m² or W/ft²) or as **Normalised power density** (W/m²-100lux or W/ft²-fc) or as **Absolute zone power** (in W).

The fuel is assumed to be *electricity*.

Power density

When the **1-Power density** [Lighting gain units](#) model option is selected gains are entered in W/m² or W/ft².

Note: When loading lighting data from template and using the **1-Power density** option, the actual lighting gain per area is calculated by dividing the Normalised power density data in the template by the required [illuminance level](#) as currently set on the [Activity tab](#). If you select a new Activity with different illuminance level requirements, the Lighting tab does not automatically update the Power density.

Normalised power density

When the **2-Normalised power density** [Lighting gain units](#) model option is selected the maximum lighting gains are defined as W/m²-100lux or W/ft²-fc and the actual lighting energy used for the zone in the simulation is based on this value plus floor area and illuminance requirements as follows:

Max Lighting power (W) = Lighting energy (W/m²-100lux) x Zone floor area (m²) x [Zone Illuminance requirement](#) / 100

Absolute zone power

When the **3-Absolute zone power** [Lighting gain units](#) model option is selected the lighting gains are defined as W without reference to the zone floor area. This option used when the actual absolute lighting gains levels are known in W. Unless you need to enter specific known lighting equipment gains zone by zone, this option is best avoided as it increases the amount of work involved due to the inheritance mechanism not working effectively for gains that are not normalised by floor area.

Calculations

For all of the above 3 options, the lighting energy should be the maximum electrical power input to lighting in a zone, including ballasts, if present. This value is multiplied by a schedule fraction (below) during the simulation to get the lighting power in a particular time step.

The electrical input to lighting ultimately appears as heat that contributes to zone loads or to return air heat gains. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Return Air Fraction, Fraction Radiant and Fraction Visible. A fourth, defined as the fraction of the heat from lights convected to the zone air, is calculated by EnergyPlus as:

Convected Fraction = 1.0 – (Return Air Fraction + Radiant Fraction + Visible Fraction)

Note: An error message is displayed if Return Air Fraction + Radiant Fraction + Visible Fraction exceeds 1.0. These fractions depend on the type of lamp and luminaire, whether the luminaire is vented to the return air, etc.

Schedule

If the [Internal gains operate with occupancy](#) model option is not set (the default state) then General lighting operation is governed by the operation schedule selected here.

The level of lighting gains are multiplied by the time-varying factor in the schedule to give the gain for each timestep in the simulation. Otherwise, if the [Internal gains operate with occupancy](#) model option is set then these gains are synchronised with the [Occupancy schedule](#).

Luminaire type

Select from:

When you select using the drop-down list an appropriate set of defaults for the luminaire type is loaded according to the table below, assuming fluorescent lighting.

Data	1-Suspended	2-Surface Mount	3-Recessed	4-Luminous and Recessed Ceiling	5-Return-air Ducted
Return Air Fraction	0.0	0.0	0.0	0.0	0.54
Radiant Fraction	0.42	0.72	0.37	0.37	0.18
Visible Fraction	0.18	0.18	0.18	0.18	0.18
Convected Fraction	0.40	0.10	0.45	0.45	0.10

Approximate values of Return Air Fraction, Radiant Fraction and Visible Fraction for overhead fluorescent lighting for different luminaire configurations. These values assume that no light heat goes into an adjacent zone. Source: *Lighting Handbook: Reference & Application, 8th Edition, Illuminating Engineering Society of North America, New York, 1993, p. 355.*

See below for more [Luminaire Performance Data](#).

Return air fraction

For Return Air Ducted luminaires this is the fraction of the heat from lights that is convected out of the room and into the zone return air (normally into a return plenum). If the return air flow is zero or the zone has no return air system, the program will put this fraction into the zone air. Return Air Fraction should normally be greater than zero for **5-Return-air ducted** luminaires. This value is not used for non-return air ducted luminaires, i.e. for **Luminaire types** 1-4.

Radiant fraction

The fraction of heat from lights that goes into the zone as long-wave (thermal) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according the area times thermal absorptance product of these surfaces.

Fraction visible

The fraction of heat from lights that goes into the zone as visible (short-wave) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according the area times solar absorptance product of these surfaces.

Note: selecting an option from the **Luminaire type** drop-down list loads default Return Air Fraction, Radiant Fraction and Visible Fraction data from the table above.

Fraction convected

The fraction of the heat from lights convected to the zone air is calculated from:

Fraction convected = 1.0 – (Return Air Fraction + Fraction Radiant + Fraction Visible)

You will get an error message if Return Air Fraction + Fraction Radiant + Fraction Visible exceeds 1.0.

This data is provided on screen for information purposes.

Luminaire Performance Data

Data on luminaire performance can also be obtained from ASHRAE Fundamentals 2013, 18.6 Table 3:

Table 3 Lighting Heat Gain Parameters for Typical Operating Conditions

Luminaire Category	Space Fraction	Radiative Fraction	Notes
Recessed fluorescent luminaire without lens	0.64 to 0.74	0.48 to 0.68	• Use middle values in most situations • May use higher space fraction, and lower radiative fraction for luminaire with side-slot returns • May use lower values of both fractions for direct/indirect luminaire • May use higher values of both fractions for ducted returns
Recessed fluorescent luminaire with lens	0.40 to 0.50	0.61 to 0.73	• May adjust values in the same way as for recessed fluorescent luminaire without lens
Downlight compact fluorescent luminaire	0.12 to 0.24	0.95 to 1.0	• Use middle or high values if detailed features are unknown • Use low value for space fraction and high value for radiative fraction if there are large holes in luminaire's reflector
Downlight incandescent luminaire	0.70 to 0.80	0.95 to 1.0	• Use middle values if lamp type is unknown • Use low value for space fraction if standard lamp (i.e. A-lamp) is used • Use high value for space fraction if reflector lamp (i.e. BR-lamp) is used
Non-in-ceiling fluorescent luminaire	1.0	0.5 to 0.57	• Use lower value for radiative fraction for surface-mounted luminaire • Use higher value for radiative fraction for pendant luminaire

Source: Fisher and Chantrasrisalai (2006).

The Space fraction in the above table from ASHRAE is the fraction of the gain entering the room and corresponds to 1 - Return air fraction.

Also, approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible for overhead fluorescent lighting for a variety of luminaire configurations are provided below. The data is based on ASHRAE 1282-RP "Lighting Heat Gain Distribution in Buildings" by Daniel E. Fisher and Chanvit Chantrasrisalai.

Fixture No.	Luminaire Feature	Return Air Fraction	Fraction Radiant	Fraction Visible	fconvected
1	Recessed, Parabolic Louver, Non-Vented, T8	0.31	0.22	0.20	0.27
2	Recessed, Acrylic Lens, Non-Vented, T8	0.56	0.12	0.20	0.12
3	Recessed, Parabolic Louver, Vented, T8	0.28	0.19	0.20	0.33
4	Recessed, Acrylic Lens, Vented, T8	0.54	0.10	0.18	0.18
5	Recessed, Direct/Indirect, T8	0.34	0.17	0.16	0.33
6	Recessed, Volumetric, T5	0.54	0.13	0.20	0.13
7	Downlights, Compact Fluorescent, DTT	0.86	0.04	0.10	0.00
8	Downlights, Compact Fluorescent, TRT	0.78	0.09	0.13	0.00
9a	Downlights, Incandescent, A21	0.29	0.10	0.6	0.01
9b	Downlights, Incandescent, BR40	0.21	0.08	0.71	0.00
10	Surface Mounted, T5HO	0.00	0.27	0.23	0.50
11	Pendant, Direct/Indirect, T8	0.00	0.32	0.23	0.45
12	Pendant, Indirect, T5HO	0.00	0.32	0.25	0.43

Task And Display Lighting

[Lighting tab in model data](#)

Task and Display Lighting accounts for lighting used for specific tasks (e.g. desk lamps) or for displaying items (e.g. display lighting for goods in shops).

Note: Task and Display Lighting is not offset by lighting control.

The following other data is assumed:

Data	Value
------	-------

Radiant fraction	0.42
Visible fraction	0.18
Return air fraction	0

Gain

Enter the gain due to task and display lighting (in W/m² or W/ft²).

Note that when you load lighting data from template, the [Default lighting display density lighting gain](#) value on the Activity tab is copied here overriding any previously set value.

Operation

If 'Internal gains operate with occupancy' under model options is not set Task lighting has a specific operation schedule set under Task Lighting, otherwise these gains are synchronised with occupancy.

Lighting Control

[Lighting tab in model data](#)

You can control the electric lights according to the availability of natural daylight. When Lighting control is switched on, illuminance levels are calculated at every time step during Simulations and Cooling design calculations and then used to determine how much the electric lighting can be reduced. The daylight illuminance level in a zone depends on many factors, including sky condition, sun position, photocell sensor positions, location, size, and glass transmittance of windows, window shades and reflectance of interior surfaces. Reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled and type of lighting control.

Tip: When running Cooling design calculations you may prefer to size without lighting control, in which case you should switch the option off at building level and clear to default to ensure it is off in all zones.

Note: You should not use daylight control in zones without any windows - this will generate errors preventing calculations from running. You should therefore use the building and block level lighting control setting with care, checking for any zones without windows and switching off lighting control at the zone level.

Lighting control is available for [General lighting](#) but not for [Task and display lighting](#). If no general lighting is specified then lighting control won't be applied.

See also the [Lighting data and daylight controls](#) tutorial

Lighting Areas

When lighting control is switched on, by default all of the lights in the zone are controlled by the first (main) lighting sensor and **% Zone Controlled by Lighting Area 1** has value 100%. Some larger spaces may have **2 Lighting Areas**, each area having its own lighting sensor and covering its own area of the zone. The area is not defined geometrically in DesignBuilder - it simply reflects the fraction of the total General overhead electric lighting that can be dimmed by its lighting sensor.

You may wish to use 2 Lighting Areas for these situations:

1. A large zone may need more than one sensor if the output from main sensor does not represent the daylight available in other parts of the zone. For example a zone having facades in both South and East directions would need 2 sensors (and 2 Lighting Areas), one on each facade.
2. The zone has 2 different activity areas which have been lumped into a single zone for convenience. The 2 activities have different visual illuminance requirements and the Lighting Areas for both can benefit from daylighting through daylighting control. An example would be a zone having both office and recreational space. The office space may have a lighting requirement of 500 lux and the recreational space may need 300 lux.

Note 1: if the zone has a different sensor for the back half (for example) you should check the **Second light sensor** option.

Note 2: if the zone has **perimeter and core areas**, perimeter lights having daylight control and core lights not, then you only need to use a single lighting sensor. The fact that the core lights are not controlled can be modelled using **% Zone Controlled by Lighting Area 1**. If 60% of the lights in the zone are located in the core zone and do not have daylight control then set **% Zone Controlled by Lighting Area 1** to 40.

Perimeter Area

A typical perimeter area would be the areas of the zone that are close to a window. By convention perimeter areas are defined as the area within a fixed distance from a normal to the perimeter. In the UK NCM the fixed distance is 6m.

If you wish to create a separate thermal zone to model the different lighting and solar conditions in the perimeter area, you can use the [Offset snap](#) option to draw [Virtual partitions](#).

Daylight illuminance on the 'working plane' is calculated for up to two locations in each zone during the simulation and [illuminance setpoints](#) are maintained where necessary by [electric lighting](#). The sensor is always located in the [working plane](#) which, by default, is 0.8m above the floor. By default, when lighting control is switched on, a single photo sensor monitors the daylight illuminance at the first sensor location and controls the lights for the whole of the zone. You can however set up 2 **Lighting Areas** in each zone, by checking the **Second lighting area** check box. In this case you can set a target illuminance for the second lighting area separately and also define the percentage of the zone covered by Lighting Area 2.

Note 1: the floor area covered by the 2 sensors does not need to add to 100%. The lights in the remaining floor area operate without daylight control.

Note 2: the target illuminance for Lighting Area 1 is set on the Activity tab under [Environmental Control](#).

If there is only one lighting area then a percentage equal to

$$100 - (\% \text{Zone covered by Lighting Area 1})$$

is assumed to have no lighting control..

% Zone Controlled by Lighting Area 2

The fraction of the zone floor-area whose electric lighting is controlled by the daylight illuminance on the second sensor. This data is required if Lighting Area 2 is being used. A percentage equal to

$$100 - [\% \text{Zone Controlled by Lighting Area 1}] - [\% \text{Zone Controlled by Lighting Area 2}]$$

is assumed to have no lighting control (i.e. in this uncontrolled area of the space, the lights operate purely according to the schedule without any dimming/switching).

Procedure

The procedure for introducing the lighting control is:

1. Check the **Lighting Control On** checkbox (at building level if all zones are to have lighting control).
2. Enter the working plane height which should normally be the height of the lighting control sensor above the top of the floor surface of the zone.
3. Select the type of control as described below.
4. [Position the first sensor](#) in each zone having lighting control. The z-position is set by the [Working plane height](#) on the Advanced tab of the Model options dialog.
5. Set the **% Zone covered by Lighting Area 1**. If all the lights in the zone are in Lighting Area 1 (i.e. they are controlled by the 1st (main) lighting sensor) then enter 100%.
6. If there are two lighting areas then [position the second sensor](#).
7. Set the **% Zone covered by Lighting Area 2**. If all the lights in the zone are in Lighting Area 2 (i.e. they are controlled by the 2nd lighting sensor) then enter $100 - \% \text{Zone covered by Lighting Area 1}$.

Note: by default the main lighting sensor is positioned in the geometric centre of the zone. It is important that you check the position of all lighting sensors to obtain accurate results. For example, if the lighting sensor is positioned right next to a window receiving large amounts of daylight, the lighting sensor will signal 'enough daylight' even if the rest of the zone is only dimly lit and electric lighting energy will be underestimated (daylight savings over-estimated).

Linear Control

With **Linear** control, the overhead lights dim continuously and linearly from maximum electric power, maximum light output to minimum electric power, minimum light output as the daylight illuminance increases. The lights stay at the minimum point with further increase in the daylight illuminance.

The **Minimum input power fraction** for **Linear** control type is the lowest power the lighting system can dim down to, expressed as a fraction of maximum input power. For **Linear/off** lighting control, this is the power fraction reached just before the lights switch off completely.

The **Minimum output fraction** for **Linear** control type, is the lowest lighting output the lighting system can dim down to, expressed as a fraction of maximum light output. This is the fractional light output that the system produces at minimum input power. For **Linear/off** lighting control, this is the light output fraction reached just before the lights switch off completely.

Note: Linear control provides an idealised lighting control mechanism which can be useful for calculating upper limits on the potential for savings when using natural daylight to offset electric lighting.

Linear/Off Control

Linear/off control is the same as Linear control except that the lights switch off completely when the minimum dimming point is reached.

Stepped Control

Stepped control allows you to switch lighting on/off according to the availability of natural daylight in discrete steps. Whereas the Linear control described above provides precisely controlled illuminance by dimming the lights, the stepped control models blocks of lights switching on/off according to the electric lighting requirement.

The electric power input and light output vary in discrete, equally spaced steps. The number of steps can be set.

Example of a Stepped Lighting Control System with 3 Steps:

Daylight illuminance	Fraction of lights that are on
0-200	1.0
200-400	$\frac{2}{3}$
400-600	$\frac{1}{3}$
600 and above	0.0

Graphical representation of above example:

See also [EnergyPlus Daylight Calculations](#).

Glare

Maximum allowable glare index

If a daylight zone has windows with [Window shading devices](#), the shades will be deployed if the daylight glare at sensor 1 exceeds the value of Maximum allowable glare index. To get this type of glare control you have to specify [Shading control type](#) as **5-Glare** for one or more windows in the zone (see [Window Shading Control](#)).

Recommended Values of Maximum Allowable Discomfort Glare Index:

Activity or zone type	Maximum Allowable Discomfort Glare Index*
Art Galleries	16
Factories	
Rough work	28
Engine assembly	26
Fine assembly	24
Instrument assembly	22
Hospital wards	18
Laboratories	22
Museums	20
Offices	22
School classrooms	20

*Source *EnergyPlus documentation*

View angle relative to y-axis

Daylight glare from a window depends on occupant view direction. It is highest when you look directly at a window and decreases as you look away from a window. This field specifies the view direction for calculating glare. It is the angle, measured clockwise in the horizontal plane, between the positive y-axis and the occupant view direction, i.e. it is the bearing of the persons line of sight. For example, with [Site orientation](#) = 0, in the Northern Hemisphere, 90 = Facing East, 180 = Facing South etc).

Algorithms

By default, DesignBuilder uses the EnergyPlus Daylighting:Detailed object to model the control of electric lighting according to daylight illumination levels. You can find more information on the algorithms used in the [EnergyPlus Daylight Calculations](#) section.

Output

For any zone simulated with daylighting controls, an illuminance map can be output with a 10 x 10 grid of additional daylighting reference points. The resulting map is output as a comma delimited text file called eplusmap.csv in the [EnergyPlus folder](#). This file can be imported into a spreadsheet program for rapid visualisation of the daylighting illuminance patterns in a zone. To generate this file, at least one zone must have daylight control and the Daylight map output selection on the Output tab of the Simulation output options dialog must be made.

Setting The Position Of Daylight Sensors

Working plane height

You can set the height of the working plane (otherwise known as desk height) to define the z-position of the lighting sensor. The x-y coordinate is set by [moving the lighting sensor](#) marker(s) at zone level.

The **Working plane height** is used for EnergyPlus daylighting simulations only and is not used in Radiance daylighting where a separate value is defined on the [Daylighting calculation options dialog](#).

Horizontal Position

To calculate the default position of the first and second daylight sensors DesignBuilder follows these steps:

1. For zones that are non-convex (zones where some surfaces cannot see all of the other surfaces in the zone, e.g. L-shaped zone) the floor plan is broken down into the smallest possible number of convex areas.
2. The geometric centre of the largest of the convex areas derived in step 1 is used as the basis for the position of the lighting sensors.
3. The specific position of the first and second sensors are 0.5m to the "left" and "right" of the geometric centre position derived in step 2.

You can move the sensor by following these steps:

1. Move to the zone level on the layout tab.
2. Select the sensor you wish to move. This enables the Move toolbar icon. You will only see the daylight sensor if lighting control is active in the current zone.
3. Click on the [Move](#) toolbar icon to start the move process.
4. Click once to define the reference or 'handle' position and click again to define the new position for the sensor.

If the second sensor is enabled in the zone then you will be able to position that in the same way.

See also: [Placing Light Sensors](#)

Exterior Lighting

[Lighting tab](#) in model data

Exterior lighting allows you to account for the energy consumption of lights used to illuminate the exterior of the building. Options are available for scheduled operation and nighttime switching.

Operation schedule

The schedule allows the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule are applied to the design level data below.

Design level

This data is normally used to represent the maximum electrical input to exterior lighting fixtures that is then multiplied by a schedule fraction (see previous field). Alternatively, the lighting design level could be a "diversity factor" applied to a schedule of real numbers.

Control Option

This data is used to determine how the exterior lights are controlled. There are currently two options:

- **Schedule only** where the exterior lights always follow the operation schedule.
- **Schedule + override off on daytime** where the exterior lights will not run when the sun is up, no matter what the schedule indicates. Using this option makes it simple to model exterior lights that are controlled by a photocell or other controller that ensures that outdoor lights will not run during the daytime. However, this control works off of the position of the sun and therefore does not operate exactly like a photocell. During the night, the schedule values are still applied in the usual way.

Lighting Cost

[Lighting tab in model data](#)

The electric lighting cost is calculated zone by zone by multiplying the zone floor area by the cost per floor area (GIFA) for the zone on the Lighting tab. This data will normally be loaded from the Lighting template to ensure that lighting performance and cost data are consistent.

Tip: The [Cost data](#) help topic provides an overview of the places in DesignBuilder where costs are entered.

Cost per area

Enter the cost per floor area (GIFA) for the lighting system.

HVAC Model Data

[HVAC tab in model data](#)

Templates

You can load generic HVAC data by clicking on the Template option under HVAC Template and then by clicking on the '...' at the right of the line.

When you make a selection from the list of [HVAC templates](#), data from selected template will be loaded to the model.

HVAC Template	
Template	Fan Coil Unit (4-Pipe), Air cooled Chiller
System	Default

System

The **System** setting data is used to group zones together that are served by the same AHU in Heating and Cooling design calculations. This allows the heating and cooling capacity of the AHU to be calculated and displayed on the Cooling design and Heating design screens.

By default DesignBuilder provides a single System called **Default** and all zones are allocated to it. You can create new Systems and select them in the same way that any other component would be created and selected. Systems have no data other than a name.

This item is shown with a green background as it is used in Heating and Cooling design calculations only.

The rest of the HVAC help section is split into 2 main sections covering the 2 HVAC model options:

- [Simple HVAC](#)
- [Detailed HVAC](#)

Also, independent of HVAC model options:

- [Natural Ventilation](#)
- [Earth Tubes](#)
- [Domestic Hot Water](#)
- [Air Temperature Distribution](#)

See also the [Simple HVAC Data](#) tutorial

Simple HVAC

[HVAC tab in model data - Simple HVAC](#)

Simple HVAC is suitable for use at early design stages or for other analyses where detailed treatment of heating, cooling and mechanical ventilation systems is required.

In summary, with Simple HVAC:

- Energy use is calculated based on space loads and system CoP value.
- Operational control provided by setpoints and schedules.
- Simple checkbox adds or removes the systems.
- Templates can be used to set performance characteristics of different systems.
- Auxiliaries and DHW are modelled based on schedules.
- Mech-vent, HR, nat-vent, mixed mode ventilation etc can also be modelled.

You can open headers to enter HVAC details where they are different from those loaded from the template:

- [Auxiliary Energy](#)
- [Mechanical Ventilation](#)
- [Fans](#)
- [Outside Air](#)
- [Heating](#)
- [Cooling](#)

See also the [Simple HVAC Data](#) tutorial

Auxiliary Energy

[HVAC tab in model data - Simple HVAC](#)

When using Simple HVAC, this data is used to calculate the electric energy consumption due to fans and pumps, control gear and any other HVAC-related equipment not accounted for elsewhere. The data used for this calculation depends on the [Simple HVAC Auxiliary](#) model options setting.

NCM Setting

When the [1-NCM Simple HVAC auxiliary energy calculations](#) option is set, only one data item is required to define the auxiliary energy consumption. This data is used at the zone level and the auxiliary energy consumption for the building is displayed at building level in the Simulation results as **Auxiliary Energy**.

Auxiliary energy

The total annual Auxiliary energy consumption can be entered as kWh/m² (SI units) or Btu/ft² (IP units). Auxiliary energy accounts for any additional energy consumption due to fans, pumps, control gear etc. It is specified per floor area and is modelled as being consumed 24/7 during the simulation. Note that when using the NCM option, auxiliary energy consumption will not vary according to mechanical ventilation flow rates or any other settings - it is a very basic way to account for auxiliary energy consumption.

The default auxiliary energy method is based on that published in the UK National Calculation Methodology (NCM).

The energy consumption related to Auxiliary energy is shown at building level on the Simulation results screen.

Separate Fans And Pumps Setting

When the [2-Separate fans and pumps Simple HVAC auxiliary energy calculations](#) option is set, the auxiliary energy calculations are carried out separately for fans and pumps and their respective energy consumption values are displayed separately in the simulation results.

- **Fan energy** is calculated based on fan pressure rise and efficiency values as defined under [Mechanical ventilation](#) > [Fans](#). The fan energy consumption data is displayed in simulation results as **Fan energy** and will depend on the actual mechanical ventilation flow rates applied in the simulation.
- **Pump**, control and any other electrical energy associated with the HVAC system is calculated using a power density value (W/m² or W/ft²) plus a schedule to define time/seasonal variations.

Pump etc energy

The pump energy can be defined as a power density (W/m² or W/ft²) and this is multiplied by the value of the associated schedule (below) to calculate the pump energy for each zone at any time in the simulation. The data is used at the zone level and the total energy consumption for the building is displayed at building level in the Simulation results as **Pump energy**.

When the [Mechanical ventilation method](#) model option is set to **1-Room ventilation**, fans are modelled in EnergyPlus based on the [Room ventilation](#) pressure and efficiency settings and the energy consumption of the fans and pumps are reported separately in results. When the [Mechanical ventilation method](#) option is set to **2-Ideal loads** EnergyPlus does not model fan energy consumption separately and in this case the total consumption of fans and pumps should be entered under **Pumps etc** and the results are reported under "Pumps".

Schedule

Select the schedule defining the time variation of the pump energy consumption.

Mechanical Ventilation

[HVAC tab in model data - Simple HVAC](#)

Check the mechanical ventilation checkbox to indicate that outside air and/or re-circulated air is delivered to the zone. You can use this setting to define mechanical ventilation and air delivered through centrally ducted air conditioning systems or local fresh air systems.

The way that mechanical ventilation is modelled in Simple HVAC depends on the [Mechanical ventilation method](#) model option:

- [1-Room ventilation](#) where mechanical ventilation is modelled using the EnergyPlus *ZoneVentilation:DesignFlowRate* data separate from the main HVAC system. This allows fan energy and heat pick up to be modelled and also more sophisticated zone temperature controlled mechanical ventilation. Heat recovery, economiser and humidity controls are not available with this option though.
- [2-Ideal loads](#) where mechanical ventilation is modelled using the EnergyPlus *ZoneHVAC:IdealLoadsAirSystem* data, allowing the effects of heat recovery, economiser and humidity control to be modelled but not fan energy and heat pickup.

Note: The specification of mechanical ventilation outside air delivery rates is the same for both options as described in the [Outside air](#) section.

1-Room Ventilation

With the [Mechanical ventilation method](#) model option the introduction of outside air through fans is achieved using the EnergyPlus *ZoneVentilation:DesignFlowRate* data separate from the main HVAC system. Energy consumption and heat pick up from fans is included as described below.

Fan Type

When using Simple HVAC, enter the type of fan. Select from:

- **1-Supply** - fan blows outside air into the zone and the zone receives heat from the fan if **Fan in air** (below) > 0
- **2-Extract** - fan exhausts air from the zone. In this case there is no fan heat pickup and it is not possible to enter Fan pressure rise and Fan total efficiency. It is assumed that makeup air comes from outside.

Note: In Simple HVAC the [Auxiliary energy](#) data accounts for all electric fan and pump distribution EnergyPlus controls and any other electrical energy use associated with HVAC that is not already accounted for elsewhere.

Fan pressure rise

When the Fan type is **1-Supply**, enter the pressure rise at full flow and standard conditions. Standard conditions are considered 20°C at sea level, 101325 Pa.

See also [Calculating Fan Pressure Rise](#).

Fan total efficiency (%)

When the Fan type is **1-Supply**, enter the product of the fan motor and impeller efficiency of the supply fan. This is the ratio of the power delivered to the air to the electrical input power at maximum flow expressed as a percentage. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The fan efficiency is power delivered to the air divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. Must be greater than 0 and less than or equal to 100.

Fan power and temperature pick up calculations

The calculations for fan power and airflow temperature pick up are detailed in the [EnergyPlus Engineering Document](#). A summary is shown below:

Total Fan Power = Mass flow rate. DeltaP / (Total fan efficiency . Air density)

Shaft Fan Power = Motor efficiency . Total Fan Power

Heat to air = Shaft Fan Power + (Total Fan Power - Shaft Fan Power) . Motor in air fraction

2-Ideal Loads

With the **Ideal loads** option, Mechanical ventilation is modelled with heating and cooling using the EnergyPlus *ZoneHVAC:IdealLoadsAirSystem* data. In this case there are options to include the effects of heat recovery, economiser, humidification and dehumidification.

Note: With the **Ideal loads** option, fan energy and heat pickup are not included in the simulation. In this case you can approximate fan energy using [auxiliary energy](#) data but if you need more detailed fan modelling you should use either the [Room ventilation](#) option or [Detailed HVAC](#) model options.

Economiser

Economisers are used to provide cooling when the outdoor temperature is lower than the indoor temperature. An economiser is a damper opening that draws up to 100% outside air when the outside air is cooler than the temperature inside the building, thereby providing **free cooling**. An outdoor air economy cycle can reduce cooling energy requirements by some 20% to 30%, or around 5% of the air conditioning energy use and are often required by energy codes for larger air conditioning units.

Choose from 3 options:

- **1-None** where no economiser operation will be simulated and outside fresh air is based purely on the Mechanical ventilation Outside air rate and associated operation schedule.
- **2-Differential dry bulb** the economiser increases the outdoor air flow rate above the minimum outdoor air flow when there is a cooling load and the outdoor air temperature or enthalpy is below the zone exhaust air temperature.
- **3-Differential enthalpy** the economiser increases the outdoor air flow rate above the minimum outdoor air flow when there is a cooling load and the outdoor air enthalpy is below that of the zone exhaust air.

Note: The economiser works together with the cooling system and if cooling is not selected the economiser will not operate.

Max outdoor air rate when economiser operates

The upper limit of outside airflow when the economiser is working in ac/h. The default is 15 ac/h.

Note: This value is not used a) when the [Cooling limit type](#) is set to **2-Limit capacity** and b) when the [HVAC Autosize](#) model option is **1-Adequate**.

Heat recovery

When heat recovery is active you can choose the type of heat recovery. Select from:

- **1-Sensible** which provides sensible heat recovery whenever the zone exhaust air temperature is more favourable than the outdoor air temperature.
- **2-Enthalpy** where latent and sensible heat recovery are provided whenever the zone exhaust air enthalpy is more favourable than the outdoor air enthalpy.

With the EnergyPlus Ideal loads system used in Simple HVAC heat recovery heating is only available when a zone is heated, i.e. when the **Heated** checkbox is checked on the HVAC tab. Likewise cooling heat recovery will only be available if the **Cooled** checkbox is checked. That is not to say that heat recovery isn't available for zones with heating at times when the heating system is not operating - heat recovery heating is available at any time in this case when the outside air is cooler than zone exhaust air, regardless of whether heating is operating or not. If you need to model heat recovery for systems without heating then you should use Detailed HVAC which is more flexible.

Sensible heat recovery effectiveness

The sensible heat recovery effectiveness, where effectiveness is defined as the change in supply temperature divided by the difference in entering supply and relief air temperatures. The default is 0.70.

Latent heat recovery effectiveness

The latent heat recovery effectiveness, where effectiveness is defined as the change in supply humidity ratio divided by the difference in entering supply and relief air humidity ratios. The default is 0.65.

Outside Air

[HVAC tab](#) in model data under [Mechanical Ventilation](#) header - Simple HVAC

You can set the amount, timing and control of outside air delivery through the HVAC air distribution system on the HVAC tab.

Outside air requirement data is used at the **zone** level for all HVAC configurations and options, though defaults settings can be made at building and block levels.

The [Mech Vent + Nat Vent + Infiltration](#) output data can be displayed on the [Heating design](#), [Cooling design](#) and [Simulation](#) screens when you select **1-All** or **3-Comfort** data. This is the sum of fresh air delivered through the HVAC system, infiltration and natural ventilation outside airflow in air changes per hour (ac/h) and when used together with the other environmental output it can be very useful in checking for occupant discomfort.

Outside air definition method

Defines the method used to set the *maximum outside air* delivery rate. The actual outside air flow rate during simulation is modified by the [Operation schedule](#) described below. The options are:

- **1-By zone** - enter the zone **outside air** delivery rate in air changes per hour in the control directly below. The air flow rate in m3/s is calculated from the ac/h data using:

$$\text{m3/s} = \text{ac/h} \times \text{ZoneVolume} / 3600$$

where:

`ZoneVolume` is the actual air volume of the space calculated according to Model options for [excluding floor/ceiling constructions](#).

Note: this zone volume may be slightly different from the value used for the purposes of calculating air flow rates for [infiltration](#) which uses the *total* zone volume.

- **2-Min fresh air (Per person)** - maximum mechanical ventilation rate is defined using [Minimum fresh air requirements](#) per person as set on the [Activity](#) tab. The air flow rate in m3/s is calculated from this as:

$$\text{m3/s} = \text{MinFreshAir}_{\text{per person}} \times \text{NumberPeople} / 1000$$

where:

`NumberPeople` = Occupancy density (people / m2) * Zone floor area (m2).
`MinFreshAirper person` is the minimum fresh air rate per person (l/s/person or CFM).

- **3-Min fresh air (Per area)** - maximum mechanical ventilation rate is defined using [Minimum fresh air requirements](#) as set on the [Activity](#) tab. The air flow rate in m3/s is calculated as:

$$\text{m3/s} = \text{MinFreshAir}_{\text{per area}} \times \text{ZoneFloorArea} / 1000$$

where:

ZoneFloorArea is the actual floor area of the space.

MinFreshAir_{per area} is the minimum fresh air rate per floor area (l/s-m2 or CFM/ft2).

- **4-Min fresh air (Sum per person + per area)** - maximum mechanical ventilation rate is defined using [Minimum fresh air requirements](#) for both as set on the [Activity](#) tab. The air flow rate in m3/s is calculated as:

$$\text{m3/s} = (\text{MinFreshAir}_{\text{per area}} \times \text{ZoneFloorArea} + \text{MinFreshAir}_{\text{per person}} \times \text{NumberPeople}) / 1000$$

where:

ZoneFloorArea is the actual floor area of the space.

MinFreshAir_{per area} is the minimum fresh air rate per floor area (l/s-m2 or CFM/ft2).

NumberPeople = Occupancy density (people / m2) * Zone floor area (m2).

MinFreshAir_{per person} is the minimum fresh air rate per person (l/s/person or CFM).

- **5-Min fresh air (Max per person and per area)** - maximum mechanical ventilation rate is defined using [Minimum fresh air requirements](#) for both as set on the [Activity](#) tab. The air flow rate in m3/s is calculated as:

$$\text{m3/s} = \text{Maximum of } (\text{MinFreshAir}_{\text{per area}} \times \text{ZoneFloorArea} / 1000) \text{ and } (\text{MinFreshAir}_{\text{per person}} \times \text{NumberPeople} / 1000)$$

where:

ZoneFloorArea is the actual floor area of the space.

MinFreshAir_{per area} is the minimum fresh air rate per floor area (l/s-m2 or CFM/ft2).

NumberPeople = Occupancy density (people / m2) * Zone floor area (m2).

MinFreshAir_{per person} is the minimum fresh air rate per person (l/s/person or CFM).

- **6-Design flow rate** - where the maximum mechanical ventilation rate is defined directly in m3/s or ft3/min.
- **7-Indoor air quality procedure** - choose this option when using Detailed HVAC to simulate a DCV system where CO2 is controlled in the zone. See "DCV Modelling" on page 2145 for a worked example.

Outside air flow rate

Enter the minimum zone **outside air** delivery rate (in air changes per hour) when **Outside air definition method** (above) is **1-By zone**.

The actual minimum amount of outside air entering the AHU can be modified by the **Operation schedule** (below).

Note: For [Heating design calculations](#), the **Outside air flow rate** value is used [unmodified](#) by a schedule when mechanical ventilation is switched on and [included](#) in the analysis.

Operation

Schedule

Select the schedule that defines the time-varying operation of the mechanical ventilation system. The fractional values in the schedule are multiplied by the **Outside air flow rate** (above).

Heating

[HVAC tab in model data - Simple HVAC](#)

The data required to define the heating system will depend on whether the [HVAC model option](#) is set to [Simple](#) or [Detailed](#) and if using Detailed the type of Detailed HVAC system selected.

Note: for all systems, [heating setpoint temperatures](#) are defined on the [Activity tab](#).

Heated

If the zone is to be heated then check this checkbox. When it is checked the rest of the items described on this page become available.

Heating capacity

The Heating capacity can be entered manually when using Simple HVAC and when the [HVAC sizing](#) model option is set to either **2-Manual** or **4-Autosize when not set**.

This setting is not available when either of the **1-Adequate** or **3- Autosize** HVAC sizing model options are selected.

When **4-Autosize when not set** is selected, if immediately prior to a [Simulation](#) the Heating capacity is not set or it has a value of zero then a DesignBuilder Heating design autosizing simulation is automatically run prior to the simulation to calculate it.

Tip: You can change heating capacities by hand if you wish, but you should bear in mind that, when **4-Autosize when not set** is selected, if the Model options or model geometry are changed, all heating and cooling capacities are reset to zero. You can set the [HVAC sizing](#) model option to **2-Manual** to avoid losing your capacity settings due to model edits.

For more information about how this works, see [HVAC sizing](#).

Heating Plant

Heating fuel

Select the type of fuel used to generate the heating energy - choose from:

Interface Fuel Name

- 1-Electricity from grid
- 2-Natural Gas
- 3-Oil
- 4-Coal
- 5-LPG
- 6-Biogas
- 7-Anthracite
- 8-Smokeless Fuel (inc Coke)
- 9-Dual Fuel Appliances (Mineral + Wood)
- 10-Biomass
- 11-Waste Heat

Fuel in results

- Electricity
- Gas
- Oil
- Solid fuel
- Bottled gas
- Bottled gas
- Solid fuel
- Solid fuel
- Other
- Other
- Other

You should select **1-Electricity from grid** you wish the results displayed in DesignBuilder to agree with those calculated by EnergyPlus directly for District heating and displayed on the Summary tab of the Simulation screen.

Heating system CoP

The heating system Coefficient of Performance is used to calculate the fuel consumption required to meet heating demand. The value represents the total seasonal efficiency of the entire heating system and should include the effect of all energy consumption associated with building heating such as any boiler fan energy, boiler inefficiency, control equipment etc. It does not include energy involved in air or water distribution (fans or pumps) or control gear, which is accounted for in the [Auxiliary energy](#).

Heating system CoP data is specified by zone so you can model different heating efficiencies in each zone. But generally you should access this data from the building level and allow zones to take on building default.

Note: When comparing the heating fuel consumption results with the data displayed on the [Summary](#) tab, it is important to realise that DesignBuilder applies a fuel type and a CoP to the idealised heating systems used in EnergyPlus when using Simple HVAC. On the other hand EnergyPlus displays the unprocessed loads as **District heating** in the tables on the Summary tab. This is because the idealised systems in EnergyPlus are considered to be met directly without use of HVAC equipment through a district heating type system.

Local Heating Units

Heating type

There are two heating types available:

- **1-Convective** - the space is heated by an air system and controlled to the air temperature set point. The system is modelled using the EnergyPlus "Ideal Loads" system.
- **2-Radiative/convective units** - used for modelling general systems where a radiant heat is a factor. Allows modelling of convective systems, hot water radiator systems, underfloor heating systems, baseboard heating etc. using EnergyPlus 'High Temp Radiant System'.

1-Convective

When using [Simple HVAC](#) you can specify the heating supply air conditions of the air.

Maximum supply air delivery temperature

The maximum dry-bulb air temperature of the air supplied for heating the zone (in °C or °F).

Maximum supply air humidity ratio

The constant humidity ratio (mass of water per mass of dry air) of the warm supply air to be delivered when heating is required. The default humidity ratio is 0.0156. You should be careful to enter a value that is a valid condition, i.e. it is under the 100% saturation line on the [Psychrometric Chart](#).

Heating limit type

There are 3 ways that EnergyPlus ideal loads systems can limit zone heating capacity:

- **1-Limit flow rate** - means that the heating supply air flow rate will be limited to a flow rate value calculated based on the autosizing model option settings. When using the **3-Autosize HVAC sizing method** the flow rate limit is calculated by EnergyPlus sizing calculations. Otherwise if the DesignBuilder sizing method is used the flow rate is calculated based on the required heating capacity calculated by DesignBuilder and the **Maximum supply air delivery temperature** (above).
- **2-Limit capacity** - means that the sensible heating capacity will be limited to a capacity value calculated based on the autosizing model option settings. When using the **3-Autosize HVAC sizing method** the capacity is calculated by EnergyPlus sizing calculations. Otherwise if the DesignBuilder sizing method is used the flow rate is calculated based on the required heating

capacity calculated by DesignBuilder and the **Maximum supply air delivery temperature** (above).

- **3-Limit flow rate and capacity** - means that both flow rate and capacity will be limited to the above values.

Technical description

EnergyPlus uses the following 4 settings to define the maximum heating input for ideal loads systems:

- Maximum Heating Supply Air Temperature
- Maximum Heating Air Flow Rate,
- Maximum Sensible Heating Capacity
- Heating Limit Type

When using the default **3-Autosize HVAC sizing** Model option the "Maximum Heating Supply Air Temperature" and "Heating Limit Type" IDF fields are set using corresponding data from the HVAC tab, and the "Maximum Heating Air Flow Rate" and "Maximum Sensible Heating Capacity" fields are calculated by EnergyPlus before the simulation in the design sizing calculations.

Alternatively, when using either of the **2-Manual** or **4-Autosize when not set HVAC sizing** Model options, the "Maximum Heating Supply Air Temperature", "Maximum Sensible Heating Capacity" and "Heating Limit Type" IDF fields are set using corresponding data from the HVAC tab, and DesignBuilder calculates the corresponding "Maximum Heating Air Flow Rate" based on the user-defined [Heating capacity](#) and [Maximum supply air delivery temperature](#) data. In this case all of the 4 related IDF fields are specified in the IDF by DesignBuilder.

Or when the **1-Adequate HVAC sizing** Model option is selected, DesignBuilder sets the EnergyPlus "Heating Limit Type" IDF field to "NoLimit" which means that the heating system can meet any load. In this case the other 3 fields are not needed and so are not provided in the IDF.

In all of the above cases, apart from when the **1-Adequate HVAC sizing** Model option is selected, EnergyPlus holds values for each of the 4 settings used to define the maximum heating input for ideal loads systems, and the way these are used in the simulation is defined by the **Heating limit type** per the above descriptions.

Note: In practice this setting should not make a noticeable difference to the thermal heat balance of the zone during heating since the maximum heat delivery to the zone is already defined before the simulation and this setting simply tells EnergyPlus exactly how to apply the limit.

2-Radiant/Convective Units

When the [Simple HVAC](#), **1-Room ventilation** [Mechanical ventilation](#) and **1-DesignBuilder Simple HVAC autosizing method** model options are set you can model radiant heating systems. Set the heating system type as **2-Radiant/convective units** (above) and enter the heating radiant fraction and the way radiant heat is distributed through the space.

Important: Recent versions of EnergyPlus no longer support the radiant/convective option combined with Simple HVAC cooling systems, so if you need radiant heating and cooling in the same zone then you should switch to Detailed HVAC.

Heating radiant fraction

The fraction of the power input to the radiant heater that is actually radiant heat transfer. The fraction should be between 0 and 1. In conjunction with the Radiant distribution option, it defines the breakdown of how the power input to the heater is distributed to the rest of the zone.

Radiant distribution

The Radiant distribution allows you to control how the radiant heat from the Radiant unit is distributed around the room. Options are:

- **1-Uniform** - radiant heat is distributed uniformly around the zone.
- **2-Floor** - heat is distributed uniformly across all floors in the zone. Use this for modelling floor heating systems.

Technical Note

DesignBuilder uses the EnergyPlus 'HIGH TEMP RADIANT SYSTEM' to model radiant heating systems when in Simple HVAC mode. This system type is intended for modelling 'high-temperature' radiant sources but it can equally well be used for low temperature radiant sources.

Note: for all Simple HVAC systems, [heating setpoint temperatures](#) are defined on the [Activity tab](#).

Sizing Zone Equipment

By default EnergyPlus does not account for mechanical and natural ventilation (outdoor air) loads in Heating design calculations so the options below are provided to add an extra load for Winter design day only.

Mechanical ventilation load

Define how mechanical ventilation loads should be dealt with in Heating design calculations. Options are:

- **1-Met by zone equipment** where mechanical ventilation loads are met entirely by zone equipment and so the capacity of the zone heating systems must account for mechanical ventilation loads.
- **2-Exclude** where the mechanical ventilation loads are not met by zone heating equipment so zone heating sizing calculations can safely ignore them.
- **3-Partially met by AHU** where the mechanical ventilation loads are partially met by heating coils in the AHU but there is still some residual load to be met by zone heating equipment. In this case the supply air temperature must also be entered. See below.

Note: The default **Mechanical ventilation load** setting is **1-Met by zone equipment**. For DOAS systems which introduce air that is partially or fully pre-heated, this setting should be changed to **2-Exclude** or to **3-Partially met by AHU** to ensure that zone equipment is not oversized.

Note: This setting applies only to Heating design calculations. For Detailed HVAC simulations the [DOAS settings](#) on the HVAC zone group dialog are used instead to account for any additional loads due to mechanically supplied fresh air. For Simple HVAC the full outdoor air load is assumed when sizing heating and cooling systems, no preheat/precool is assumed when sizing zone equipment.

System supply temperature

When Mechanical ventilation load is set to **3-Partially met by AHU** then you must enter the supply air temperature to enable the residual additional zone loads required to be accounted for.

Exclude heat recovery from zone heating sizing

If the savings provided by heat recovery can be safely included in the heating sizing calculations then leave this checkbox unchecked. Otherwise for a safer calculation where zone heating systems are sized based on no heat recovery being available then check this option.

Natural ventilation load

If natural ventilation is activated then you can define how natural ventilation loads should be dealt with in Heating design and simulation autosizing simulations. Options are:

- **1-Met by zone equipment** the default option where natural ventilation loads are met entirely by zone equipment and so the capacity of the zone heating systems must account for natural ventilation loads. Note that in Heating design calculations, when this option is selected, natural ventilation will be applied without regard for schedule or [mechanical ventilation setpoint](#) temperature settings.
- **2-Exclude** where the natural ventilation loads are not met by zone heating equipment so zone heating sizing calculations can safely ignore them.

Operation

Heating operation schedule

This schedule data is used in conjunction with the [heating setpoint temperatures](#) on the [Activity tab](#) to define the time-varying heating setpoint schedule in the zone. The operation schedule defines the times when full and setback setpoints should be met and the setpoint data on the Activity tab define the actual setpoint values. See [Defining setpoint temperature schedules](#) for more on this.

Note: the zone heating operation schedule is also used in Detailed HVAC with the default **1-Simple HVAC** [Detailed HVAC Activity data](#) setting.

Cooling

[HVAC tab](#) in model data - Simple HVAC

You can enter details on the cooling system including the maximum capacity (at zone level).

Note: for all systems, [cooling setpoint temperatures](#) are defined on the [Activity tab](#).

Cooled

If the zone is to be actively cooled then check this checkbox. When it is checked the rest of the items described on this page become available.

Cooling capacity

The Cooling capacity can be entered manually when using Simple HVAC and when the [HVAC sizing](#) model option is set to either **2-Manual** or **4-Autosize when not set**.

This setting is not available when either of the **1-Adequate** or **3- Autosize** HVAC sizing model options are selected.

When **4-Autosize when not set** is selected, if immediately prior to a [Simulation](#) the Cooling capacity is not set or it has a value of zero then a DesignBuilder Cooling design autosizing simulation is automatically run prior to the simulation to calculate it.

Tip: You can change cooling capacities by hand if you wish, but you should bear in mind that, when **4-Autosize when not set** is selected, if the Model options or model geometry are changed, all heating and cooling capacities are reset to zero. You can set the [HVAC sizing](#) model option to **2-Manual** to avoid losing your capacity settings due to model edits.

For more information about how this works, see [HVAC sizing](#).

Supply Air Conditions

When using [Simple HVAC](#) you can specify the cooling supply air conditions of the air.

Minimum supply air delivery temperature

The minimum dry-bulb air temperature of the air supplied for cooling the zone (in °C or °F).

Minimum supply air humidity ratio

The minimum humidity ratio (kg of water per kg of dry air) of the cool supply air. The default is 0.0077 kg-H₂O/kg-air which corresponds to a 10C (50F) dew point. You should be careful to enter a value that is a valid condition, i.e. it is under the 100% saturation line on the [Psychrometric Chart](#).

Cooling limit type

There are 3 ways that EnergyPlus ideal loads systems can limit zone cooling capacity (for simulations only):

- **1-Limit flow rate** - means that the cooling supply air flow rate will be limited to a flow rate value calculated based on the autosizing model option settings. When using the **3-Autosize HVAC sizing method**, the flow rate limit is calculated by EnergyPlus sizing calculations. Otherwise if the DesignBuilder sizing method is used, the flow rate is calculated based on the required cooling capacity calculated by DesignBuilder and the **Minimum supply air delivery temperature** (above).
- **2-Limit capacity** - means that the sensible cooling capacity will be limited to a capacity value calculated based on the autosizing model option settings. When using the **3-Autosize HVAC sizing method** the capacity is calculated by EnergyPlus sizing calculations. Otherwise if the DesignBuilder sizing method is used the flow rate is calculated based on the required cooling capacity calculated by DesignBuilder and the **Minimum supply air delivery temperature** (above).
- **3-Limit flow rate and capacity** - means that both flow rate and capacity will be limited to the above values.

Technical description

EnergyPlus uses the following 4 settings to define the maximum cooling input for ideal loads systems:

- Minimum Cooling Supply Air Temperature
- Maximum Cooling Air Flow Rate,
- Maximum Total Cooling Capacity
- Cooling Limit Type

When using the default **3-Autosize HVAC sizing** Model option the "Minimum Cooling Supply Air Temperature" and "Cooling Limit Type" IDF fields are set using corresponding data from the HVAC tab, and the "Maximum Cooling Air Flow Rate" and "Maximum Total Cooling Capacity" fields are calculated by EnergyPlus before the simulation in the design sizing calculations.

Alternatively, when using either of the **2-Manual** or **4-Autosize when not set HVAC sizing** Model options, the "Maximum Cooling Supply Air Temperature", "Maximum Sensible Cooling Capacity" and "Cooling Limit Type" IDF fields are set using corresponding data from the HVAC tab, and DesignBuilder calculates the corresponding "Maximum Cooling Air Flow Rate" based on the user-

defined [Cooling capacity](#) and [Minimum supply air delivery temperature](#) data. In this case all of the 4 related IDF fields are specified in the IDF by DesignBuilder.

Or when the **1-Adequate HVAC sizing** Model option is selected, DesignBuilder sets the EnergyPlus "Cooling Limit Type" IDF field to "NoLimit" which means that the cooling system can meet any load. In this case the other 3 fields are not needed and so are not provided in the IDF.

In all of the above cases, apart from when the **1-Adequate HVAC sizing** Model option is selected, EnergyPlus holds values for each of the 4 settings used to define the maximum cooling input for ideal loads systems, and the way these are used in the simulation is defined by the **Cooling limit type** per the above descriptions.

Note: In practice this setting should not make a noticeable difference to the thermal heat balance of the zone during cooling since the maximum cooling delivery to the zone is already defined before the simulation and this setting simply tells EnergyPlus exactly how to apply the limit.

Cooling Plant

Cooling fuel

Select the type of fuel used to generate the cooling energy - choose from:

Interface Fuel Name

1-Electricity from grid
2-Natural Gas
3-Oil
4-Coal
5-LPG
6-Biogas
7-Anthracite

You should select **1-Electricity from grid** you wish the results displayed in DesignBuilder to agree with those calculated by EnergyPlus directly for District cooling and displayed on the Summary tab of the Simulation screen.

Cooling system CoP

The cooling system coefficient of performance is used to calculate the fuel consumption required to meet cooling demand. The value represents the total seasonal efficiency of the entire cooling system and should include the effect of all energy consumption associated with building cooling such as fan and pump energy, chiller inefficiency, control equipment etc.

Cooling system CoP data is specified by zone so you can model different cooling efficiencies in each zone. But generally you should access this data from the building level and allow zones to take on building default.

Note: When comparing the cooling fuel consumption results with the data displayed on the [Summary](#) tab, it is important to realise that DesignBuilder applies a fuel type and a CoP to the idealised cooling systems used in EnergyPlus when using Simple HVAC. On the other hand EnergyPlus displays the unprocessed loads as **District cooling** in the tables on the Summary tab. This is because the idealised systems in EnergyPlus are considered to be met directly without use of HVAC equipment through a district cooling type system.

Operation

Cooling operation schedule

This schedule data is used in conjunction with the [cooling setpoint temperatures](#) on the [Activity tab](#) to define the time-varying cooling setpoint schedule in the zone. The operation schedule defines the times when full and setback setpoints should be met and the setpoint data on the Activity tab define the actual setpoint values. See [Defining setpoint temperature schedules](#) for more on this.

Note: the zone cooling operation schedule is also used in Detailed HVAC with the default **1-Simple HVAC Detailed HVAC Activity data** setting.

Humidity Control

[HVAC tab](#) in model data - Simple HVAC

When using the Ideal loads [Mechanical ventilation method](#) you have the option to control humidity by checking the Humidification and/or Dehumidification checkboxes on the HVAC tab.

Note: In real HVAC systems humidity control can require considerable energy consumption to achieve. If you require an accurate assessment of this energy then you should consider using [Detailed HVAC humidity control](#) which allows you to track energy flows in more detail.

Humidification

Humidification control type

When humidification is selected there are 2 further options:

- **1-Constant supply humidity ratio** means that during heating the supply air will always be at the Maximum heating supply humidity ratio.
- **2-Humidistat** means that the humidity in the zone is controlled using the [Humidification setpoint](#) defined on the Activity tab. The ideal loads system will attempt to meet the humidistat request, i.e. it will humidify according to the setpoint.

Dehumidification

Dehumidification control type

When dehumidification is selected there are 3 further options:

- **1-Constant supply humidity ratio** means that during cooling the supply air will always be at the Minimum cooling supply humidity ratio.
- **2-Humidistat** means that the humidity in the zone is controlled using the [Dehumidification setpoint](#) defined on the Activity tab. The ideal loads system will attempt to meet the humidistat request, i.e. it will dehumidify according to the setpoint.
- **3-Constant sensible heat ratio** means that the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using the constant sensible heat ratio (SHR) defined below.

For **3-Constant sensible heat ratio** and **2-Humidistat** options, if the mixed air humidity ratio is less than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature. The selected dehumidification

control type is always applied when the unit is in cooling mode. If the unit is in deadband mode (not actively heating the supply air) control type Humidistat will be active. If the unit is in heating mode, control type Humidistat will be active if the Humidification Control Type field below is set to Humidistat or None. This allows the ideal loads system to heat and dehumidify at the same time.

Cooling sensible heat ratio

When the **Dehumidification control type** above is set to **3-Constant sensible heat ratio** the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using the value of Cooling Sensible Heat Ratio (SHR), where $SHR = \text{Sensible Cooling} / \text{Total Cooling (sensible plus latent)}$. The default is 0.7.

Humidity Control Linkage With Heating And Cooling Schedules

In Simple HVAC, the timing of humidification control is the same as that for heating. So at times when heating is available (in setpoint or setback mode) humidification control is also available. Likewise the timing of dehumidification control is the same as that for cooling. So at times when cooling is available (in setpoint or setback mode) dehumidification control is also available.

Detailed HVAC

HVAC tab in model data - Detailed HVAC

When the [Detailed HVAC model option](#) is selected and the [Detailed HVAC Activity](#) data model option is set to **1-Simple HVAC Data**, the HVAC tab is used to define:

- Operation/setpoint schedules (under the [Heating](#) and [Cooling](#) headers),

Note: With Detailed HVAC simulations the **Heating on** and **Cooling on** settings have no effect on simulations, other than to show/hide the schedule data. They are always used in Heating and Cooling design calculations though.

- [Outdoor air ventilation requirement](#) (under the Mechanical Ventilation header)
- "Environmental Impact Factors" on page 522
- [Natural ventilation](#) and
- [Air temperature distribution](#) settings.

Note: For heating and cooling design calculations the humidity and temperature setpoints and ventilation requirement data comes from the Activity and HVAC tabs as described under the **1-Simple HVAC** column in the [table under Detailed HVAC Activity data](#), regardless of the **Detailed HVAC Activity Data** setting.

The main HVAC data is entered by clicking on the <HVAC System> navigator node.

Further details of Detailed HVAC are provided in a [separate section](#).

Natural Ventilation

HVAC tab in model data

You can control the operation of natural ventilation using the data under the Natural Ventilation header on the HVAC tab. When using [Calculated](#) natural ventilation model option there is additional data on the [Openings](#) tab to control the timing and extent of operation of openings.

Note: the Natural ventilation checkbox must be ticked here on the HVAC tab to allow window, vent and door [operation](#) to be defined on the Openings tab.

The data shown under Natural ventilation on the HVAC tab depends on whether you are using the Scheduled or Calculated [Natural ventilation](#) setting in Model options.

- [Scheduled Natural Ventilation Data](#)
- [Calculated Natural Ventilation Data](#)

Both Scheduled and Calculated Natural ventilation options are available with both [Simple](#) and [Detailed](#) HVAC options.

- "Mixed Mode Tutorial" on page 501

Scheduled Natural Ventilation Data

[HVAC tab](#) in model data

See the [Scheduled natural ventilation and infiltration](#) tutorial

Summary of Scheduled Natural Ventilation data definition

When the [Natural ventilation model option](#) is set to **Scheduled**, and for heating and cooling design calculations, natural ventilation is defined as follows:

- Check the **On** checkbox under the Natural Ventilation header.
- Select the Outside air definition method
- Set the maximum zone natural ventilation rate in air changes per hour (if flow type is **1-By zone**), or in m³/s or ft³/min (if the flow type is **3-Design flow rate**).
- Select the operation schedule.
- Enter the relevant control parameters on the HVAC tab and on the Activity tab.

Find out more about [Natural Ventilation Modelling](#) under [Modelling Advice](#).

Natural Ventilation

Natural ventilation On

Check the **On** checkbox under the Natural Ventilation header to activate natural ventilation. This causes all of the natural ventilation data on the HVAC tab to be accessible.

Outside air definition method

The Outside air definition method allows you to select the method to be used to set the maximum outside air natural ventilation rate. The options are:

- **1-By zone** - enter the zone natural ventilation rate in air changes per hour in the control directly below. The design air flow rate is calculated from the ac/h data using:

$$V_{\text{design}} = ac/h \times \text{ZoneVolume} / 3600$$

where `ZoneVolume` is the actual air volume of the space calculated according to options for optionally [excluding floor/ceiling constructions](#).

Note: this zone volume may be different from the value used for the purposes of calculating air flow rates for [infiltration](#) which uses the *total* zone volume.

- **2-Min fresh air per person** - maximum natural ventilation rate is defined using [Minimum fresh air requirements](#) as set on the [Activity](#) tab. The design air flow rate in m3/s is calculated as:

$$V_{\text{design}} = \text{MinFreshAir} \times \text{NumberPeople} / 1000$$

`NumberPeople` = Occupancy density (people / m2) * Zone floor area (m2)

`MinFreshAir` is the minimum fresh air rate per person (l/s/person)

- **3-Design flow rate** - where the maximum natural ventilation rate is entered directly in m3/s or ft3/min.

The actual ventilation rate in m3/s is calculated at each time step of the simulation using the equation below:

$$\text{Ventilation} = V_{\text{design}} F_{\text{schedule}} [A + B (T_{\text{in}} - T_{\text{out}}) + C \cdot \text{Wind Speed} + D (\text{Wind Speed}^2)]$$

Each of the parameters A-D in the equation above are explained below under [Delta T and Wind Speed Coefficients](#).

F_{schedule} is described below under Operation > Schedule.

Operation

Schedule

Select the schedule used to modify the maximum design natural volume flow rate (V_{design}) (see Design Flow Rate Calculation Method field and related subsequent fields). This fraction between 0.0 and 1.0 is included as F_{schedule} in the above equation.

Outdoor Temperature Limits

Outdoor min temperature control

Check this checkbox if you wish to define a restriction on natural ventilation operation when outdoor temperature drops below a setpoint temperature. Use this option to help avoid over-cooling a space, which could result in a heating load.

Min temperature definition

There are 2 ways to define the outdoor min temperature:

- **1-By value** - use this option when the setpoint does not change with time in which case you can enter a fixed setpoint temperature.
- **2-By schedule** - use this option when the setpoint changes with time in which case you can select a schedule of time-varying temperature setpoints.

Outdoor min temperature

This is the fixed outdoor temperature (in °C or °F) below which ventilation is shut off. This control is visible when the **1-By value** option is selected for [Min temperature definition](#).

Outdoor min temperature schedule

This is the schedule of outdoor temperatures (in °C) below which ventilation is shut off. This control is visible when the **1-By schedule** option is selected for **Min temperature definition**.

See also [Defining setpoint temperature schedules](#).

Outdoor max temperature control

Check this checkbox if you wish to define a restriction on natural ventilation operation when outdoor temperature rises above a setpoint temperature. Use this option to help avoid over-heating a space, which could result in a cooling load.

Max temperature definition

There are 2 ways to define the outdoor max temperature:

- **1-By value** - use this option when the setpoint does not change with time in which case you can enter a fixed setpoint temperature.
- **2-By schedule** - use this option when the setpoint changes with time in which case you can select a schedule of time-varying temperature setpoints.

Outdoor max temperature

This is the fixed outdoor temperature (in °C or °F) above which ventilation is shut off. This control is visible when the **1-By value** option is selected for **Max temperature definition**.

Outdoor max temperature schedule

This is the schedule of outdoor temperatures (in °C) above which ventilation is shut off. This control is visible when the **1-By schedule** option is selected for **Max temperature definition**.

See also [Defining setpoint temperature schedules](#).

Delta T Limits

Delta T limit control

Check this option to limit natural ventilation operation based on the temperature difference between the indoor and outdoor air dry-bulb temperature. It allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space.

Uncheck this option to keep the ventilation on even if the outdoor temperature is greater than the indoor temperature. This is useful for uncontrolled natural ventilation (open windows) or as a way to estimate the effect of required ventilation air for load calculations.

Delta T definition

There are 2 ways to define the Delta T to be used in temperature difference control:

- **1-By value** - use this option when the Delta T does not change with time in which case you can enter a fixed value.
- **2-By schedule** - use this option when the Delta T changes with time in which case you can select a schedule of time-varying Delta T values.

Delta T

This is the temperature difference (in °C or °F) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shut off. This field allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. For example, if the user specifies a delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry-bulb temperature is less than 2°C

cooler than the indoor dry-bulb temperature, then ventilation is automatically turned off. The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature.

The Delta Temperature is used in the code in the following way:

IF ((IndoorTemp - OutdoorTemp) < DeltaTemperature) Then ventilation is not allowed.

For example:

Value of Natural ventilation delta T	Effect
0	Natural ventilation only operates when <i>OutdoorTemp < IndoorTemp</i>
-100	Natural ventilation unrestricted by Inside-Outside delta T
2	Natural ventilation only operates when <i>OutdoorTemp + 2 < IndoorTemp</i>

Delta T schedule

This is the schedule of temperature difference values (in °C) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shut off. See above **Delta T** description for more details.

Delta T And Wind Speed Coefficients

The coefficients below can be used to set up inside to outside Delta T and wind speed dependency of the Scheduled natural ventilation rates using the equation at the end of the [Outside air definition method](#) section.

Technical

The question of typical values for these coefficients is subject to debate. Ideally, one should do a detailed analysis of the ventilation situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. The defaults are 1,0,0,0 which give a constant volume flow of ventilation under all conditions.

The equation must always yield a non-negative results; negative values are set to 0.0. BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0C deltaT and 3.35 m/s (7.5mph) wind speed, which corresponds to a typical summer condition. At a winter condition of 40C deltaT and 6 m/s (13.4 mph) wind speed, these coefficients would increase the ventilation rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (wind speed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A wind speed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as: "Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions." The source of the DOE-2 defaults is based on examining the infiltration relationships described in the ASHRAE Handbook of Fundamentals.

The local outdoor dry-bulb temperature used in the above basic equation (T_{out}) is typically a function of the height of the zone centroid above ground. The local outdoor dry-bulb temperature calculation procedure is described in the "Local Outdoor Air Temperature Calculation" section of the Engineering Reference.

The local outdoor wind speed used in the above basic equation (Wind Speed) is also a function of the height of the zone centroid above ground. The local outdoor wind speed calculation procedure is described in the "Local Wind Speed Calculation" section of the Engineering Reference.

Constant

This constant term coefficient is the "A" parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

Temperature

The temperature term coefficient is the “B” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

Velocity

The velocity term coefficient is the “C” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

Velocity squared

The velocity squared term coefficient is the “D” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s²/m².

Summary Of Scheduled Natural Ventilation Operation Rules

Scheduled natural ventilation is active at any time in the simulation based on the rules in the table below.

Condition	Rule	Data Location
If Natural ventilation indoor min temperature control checked	Operation schedule has value > 0 AND $T_{in} > \text{Natural ventilation min temperature}$ AND	HVAC tab Activity tab
If Natural ventilation indoor max temperature control checked	$T_{in} < \text{Natural ventilation max temperature}$ AND	Activity tab
If Outdoor min temperature control checked	$T_{out} > \text{Outdoor min temperature}$ AND	HVAC tab
If Outdoor max temperature control checked	$T_{out} < \text{Outdoor min temperature}$ AND	HVAC tab
If Delta T control checked	$T_{in} - T_{out} > \text{Delta T}$	HVAC tab

Where:

T_{in} is the inside dry bulb air temperature
 T_{out} is the outside dry bulb air temperature

Note: The Outdoor temperature and Delta T control rules described on this page can be used in combination with any [indoor temperature min/max controls](#) that may also have been selected on the activity tab to set up multiple restrictions on natural ventilation operation.

Tip: To ensure that natural ventilation operates regardless of temperature inside and outside you should uncheck all of the checkbox options listed on the "Condition" column in the above table.

Internal Windows, Doors And Vents

Airflow through *external* windows, vents, doors and holes are not modelled with **Scheduled** natural ventilation because the natural ventilation airflow from outside is explicitly defined (above). Internal windows, vents, doors and holes cause air to be exchanged between the two adjacent zones using the EnergyPlus **ZoneMixing** object. The way this works can be defined on the Advanced tab of the Model options dialog under the [Natural Ventilation](#) > Scheduled headers.

In addition, you can override operation of *internal* windows, vents and doors to be **off** as follows:

Window, Vent, Door position	Override Off Action
Internal windows and vents	Use the Internal Window and Vent Operation Control option data, selecting 2-Closed .
Doors	Set the door Operation schedule to Off

Calculated Natural Ventilation Data

[HVAC tab](#) in model data

See the [Calculated natural ventilation](#) tutorial

When the [Natural ventilation model option](#) is set to **Calculated**, natural ventilation data is set up using the following procedure:

1. Check the **On** checkbox under the Natural Ventilation header.
2. On the [Openings tab](#) set window, door and vent opening sizes and operation times.

You can override the operation of windows, vents and door to be **off** as follows:

Window or Vent position	Override Off Action
External	Switch off the Natural ventilation On checkbox
Internal adjacent to unconditioned semi-exterior zone	Switch off the Natural ventilation On checkbox in the occupied zone
Other internal windows and vents	Use the Internal Window and Vent Operation Control option data, selecting 1-Control by schedule and set the schedule to Off . When using the 1-Constant Control option on the Openings tab, airflow through internal windows/vents will occur (when enabled by the operation schedule) regardless of whether natural ventilation is activated here on the HVAC tab.
Doors	Set the door Operation schedule to Off

Note that even when operation is switched off as described above, windows, vents and doors still provide a small flow path through the crack between the opening and the surrounding surface if the [Model infiltration](#) option is checked.

Note 1: For **Cooling design** calculations, natural ventilation is always handled as [Scheduled](#) even when the Natural ventilation model option is set to [Calculated](#). In this case you can still enter natural ventilation air change rates and operation schedule data on the HVAC tab but *it is used only for design simulations*. The captions for data used for design calculations only is displayed with a green background in the interface.

Note 2: With both the Scheduled and Calculated options, natural ventilation can be [overridden](#) to be off in Heating and Cooling design calculations. In Heating design calculations natural ventilation is switched off by default because it is considered to be a cooling mechanism - windows and vents will normally be closed during the coldest winter periods.

Wind Factor

When carrying out conservative design simulations you may prefer to exclude (or reduce) the effects of wind pressure from Calculated natural ventilation. To exclude wind-driven airflow from the analysis altogether set the Wind factor to 0. For full treatment of wind effects set it to 1, and for intermediate treatment of wind set it to a number between 0 and 1. You can also check the impact of increasing wind pressure by entering values greater than 1.

The wind factor entered here is used to multiply the [Wind Pressure Coefficients](#) entered at surface level when writing out the modified values for EnergyPlus.

Note: Although this setting is called "Wind factor" for convenience, it is actually used as a wind pressure coefficient multiplier. The wind pressure of a surface as calculated by EnergyPlus during simulations as:

$$\text{Wind Pressure} = C_p * 0.5 * \rho * \text{Wind Speed} * \text{Wind Speed}$$

So to obtain the effect of multiplying wind speed, you should enter a squared value here. For example, if you would like to check the impact of halving the wind speeds in the weather file you should enter $0.5^2 = 0.25$ as the Wind factor.

Control mode

For calculated natural ventilation the control mode defines the way that the exterior openings are opened and closed based on air temperatures or enthalpy. The data can be entered at building, block, zone, surface or opening level.

In the descriptions that follow:

T_{out} is the outdoor air temperature,
 T_{zone} is the previous time step's zone air temperature,
 $T_{adjacent\ zone}$ is the previous time step's air temperature for the adjacent zone for interior surfaces,
 T_{set} is the [zone natural ventilation setpoint temperature](#),
 H_{zone} is the specific enthalpy of zone air from the previous time step, and
 H_{out} is the specific enthalpy of outdoor air.

The allowed choices for natural ventilation **Control mode** are:

- **1-NoVent** - all of the zone's exterior openable windows and doors are closed at all times independent of indoor or outdoor conditions. The [operation schedule](#) is ignored in this case.
- **2-Temperature** - all of the zone's openable exterior windows and doors are opened if $T_{zone} > T_{out}$ and $T_{zone} > T_{set}$ and [operation schedule](#) allows venting.
- **3-Enthalpy** - All of the zone's openable exterior windows and doors are opened if $H_{zone} > H_{out}$ and $T_{zone} > T_{set}$ and [operation schedule](#) allows venting.
- **4-Constant** - Whenever an opening's [operation schedule](#) allows venting, all of the zone's openable exterior windows and doors are open, independent of indoor or outdoor conditions. This option is useful for modelling windows that are opened for fresh air regardless of inside/outside temperature/enthalpy. Note that "Constant" here means that the size of each opening is fixed while venting; the air flow through each opening can, of course, vary from time step to time step. As with the other control mode options, the [Operation schedule](#) defined on the Openings tab controls opening availability.
- **7-CEN 15251 Adaptive** - Openable exterior windows and door are opened if the operative temperature is greater than the comfort temperature calculated from the CEN15251 adaptive comfort model and the [Venting operation schedule](#) allows venting.
- **8-ASHRAE 55 Adaptive** - Openable exterior window and doors are opened if the operative temperature is greater than the comfort temperature calculated from the ASHRAE Standard 55-2010 adaptive comfort model and the [Venting operation schedule](#) allows venting.

Both of the Adjacent temperature control options (5 and 6) revert to **2-Temperature** when applied to exterior surfaces. This allows these options to be set at building level.

Internal control mode

The allowed choices for natural ventilation **Internal control mode** are:

- **1-NoVent** - all of the zone's interior openable windows and doors are closed at all times independent of indoor or outdoor conditions. The [operation schedule](#) is ignored in this case.
- **2-Temperature** - all of the zone's openable interior windows and doors are opened if $T_{zone} > T_{out}$ and $T_{zone} > T_{set}$ and [operation schedule](#) allows venting.
- **3-Enthalpy** - All of the zone's openable interior windows and doors are opened if $H_{zone} > H_{out}$ and $T_{zone} > T_{set}$ and [operation schedule](#) allows venting.
- **4-Constant** - Whenever an internal opening's [operation schedule](#) allows venting, all of the zone's openable exterior windows and doors are open, independent of indoor or outdoor conditions. This option is useful for modelling windows that are opened for fresh air regardless of inside/outside temperature/enthalpy. Note that "Constant" here means that the size of each opening is fixed while venting; the air flow through each opening can, of course, vary from time step to time step. As with the other control mode options, the [Operation schedule](#) defined on the Openings tab controls opening availability.
- **5-Adjacent temperature cooling** - interior windows and doors are opened if $T_{zone} > T_{adjacent\ zone}$ and $T_{zone} > T_{set}$ and [operation schedule](#) allows venting.
- **6-Adjacent temperature heating** - interior windows and doors are opened if $T_{zone} < T_{adjacent\ zone}$ and $T_{zone} > T_{set}$ and [operation schedule](#) allows venting. This option is a basic attempt to get round the EnergyPlus assumption that natural ventilation is always used for cooling and allow it to heat a zone as well. Note however that the zone setpoint is still used to switch off ventilation if the temperature goes too low (rather than too high as might be expected for a heating control).
- **7-CEN 15251 Adaptive** - Openable interior windows and door are opened if the operative temperature is greater than the comfort temperature calculated from the CEN15251 adaptive comfort model and the [Venting operation schedule](#) allows venting.
- **8-ASHRAE 55 Adaptive** - Openable interior window and doors are opened if the operative temperature is greater than the comfort temperature calculated from the ASHRAE Standard 55-2010 adaptive comfort model and the [Venting operation schedule](#) allows venting.

Note: **Internal control mode** is used in the simulation only when the Internal window or vent [Control option](#) is set to **2-Use Internal control mode**, otherwise it is ignored.

Identifying which zone is "more occupied"

For interior openings the zone temperature and setpoint used to control operation is that of the "more occupied" of the 2 adjacent zones. The rules for establishing which zone is "more occupied" are as follows:

Zone is "more occupied" if:

- If zone is occupied and adjacent zone is unconditioned, or, if the 2 zones have the same zone type then the assessment is made based on:

Zone is "more occupied" if:

- It is heated and adjacent zone is not, or otherwise,
- if both zones are heated then if it has a higher setpoint temperature, or otherwise,
- It is cooled and adjacent zone is not, or otherwise,
- if both zones are cooled then if it has a lower setpoint temperature.

If both zones have identical zone type and heating and cooling setpoints are the same then an arbitrary assignment is made.

Tip: **Control mode** data is available at surface and opening level allowing you to control different windows in different ways.

Modulation of Openings

You can modulate the window/door openings when using Calculated natural ventilation by making appropriate settings to:

- **Modulate opening areas** - switch on modulation by checking this option.
- **Limit value of opening modulation factor** - gives the reduction on opening area for low outside air temperatures.
- **Lower value of Tin-Tout** - lower value on inside/outside temperature difference for modulating the venting open factor.
- **Upper value of Tin-Tout** - upper value on inside/outside temperature difference for modulating the venting open factor (defines 'low outside air temperatures').

This data is used within EnergyPlus to calculate a factor between 0 and 1 that multiplies the opening factor of each window and door in the building. Modulation of the openings can reduce the large temperature swings that can occur if the windows/doors are too far open when they are venting, especially when there is a large inside-outside temperature difference. This can avoid discomfort due to introduction of cold air and/or prevent heating system operation in summer when not really required.

Temperature difference ($T_{in} - T_{out}$)	Opening Multiplier
$T_{in} - T_{out} \leq [\text{Lower value of } T_{in} - T_{out}]$	1.0
$[\text{Lower value of } T_{in} - T_{out}] < T_{in} - T_{out} < [\text{Upper value of } T_{in} - T_{out}]$	Factor varies linearly from 1.0 to Limit value of Opening modulation factor.
$T_{in} - T_{out} \geq [\text{Upper Value of } T_{in} - T_{out}]$	Factor = Limit value of opening modulation factor.

For example if the Lower value of $T_{in} - T_{out}$ is 0, the Upper value is 15 and the Limit value of opening modulation factor is 0.05, the windows and doors are only opened 5% of their full opening area when the outside air is 15K colder than inside. When the inside and outside temperatures are the same the windows are open to their maximum opening area and when the temperature difference is 7.5K the windows are opened halfway between these extremes.

Important Notes

1. The purpose of the Modulate option is to prevent discomfort due to very cold air being introduced into the zone. You should keep in mind though that because this control will also prevent ventilation when the temperature in the space is very hot and the outside air is not particularly cold because of the large temperature difference between inside and outside.

For example if the upper modulation temperature difference is 15K and the limiting modulation factor is 0.05 then the maximum window and vent opening area will be reduced to 5% of their normal size if the temperature in the zone is 35°C and the temperature outside is 20°C. In this case the natural ventilation through the 'almost closed' openings would probably not be adequate to cool the zone back down again. So you should not use this option if you wish natural ventilation to occur when the temperature inside is very high.

2. With Modulation active, openings will be completely closed if the difference between inside and outside air temperatures is greater than **Upper value of Tin-Tout**.
3. While the modulation graph above shows the opening factor to be 1 when the inside temperature is greater than outside temperature, by default the natural ventilation openings will all be closed in this case based on the [2-Temperature control mode](#).

This modulation data can also be accessed from the HVAC tab under the Natural Ventilation > Options headers.

Tip: Although basic DesignBuilder natural ventilation options don't allow controls based on absolute outdoor air temperature, it is possible to apply upper and/or lower outdoor air temperature limits for natural ventilation through use of the mixed mode Temperature control schedule and the [Mixed mode minimum and maximum temperatures](#).

Tip: Modulation settings are available at surface and opening level allowing you to control different windows in different ways.

Mixed Mode Zone Equipment

HVAC tab in model data

See the [Mixed mode ventilation](#) tutorial

Mixed mode on

You can include mixed mode natural ventilation (called hybrid ventilation in EnergyPlus) and HVAC [change-over](#) control for zone equipment by checking the **Mixed mode on** checkbox on the HVAC tab under the Natural ventilation header.

The mixed mode control serves two purposes:

1. Prevents simultaneous natural ventilation and HVAC system cooling operation, and,
2. Allows you to test various ventilation strategies to maximize natural ventilation in order to reduce heating/cooling loads.

The mixed mode change-over controller links the associated HVAC system with the operable windows and vents in the zones served by the HVAC system. The controller overrides the natural ventilation controls for windows and vent openings, closing these openings under when conditions are unfavourable for natural ventilation and allowing the HVAC system to operate. If the controller determines that conditions are favourable for natural ventilation, then the HVAC system is disabled and the openings are able to operate based on the standard natural ventilation control mechanism (natural ventilation setpoint, maximum opening area, modulation etc).

Mixed mode controls can be used when using either Calculated or Scheduled natural ventilation, Simple or Detailed HVAC.

Note: Mixed model data on the HVAC tab is used for a) Simple HVAC and b) zone equipment such as FCU, PTAC etc when using Detailed HVAC. This data is not used to control Detailed HVAC AHUs. The AHU mixed mode controls are on the [Air Handling Unit](#) dialog and any mixed mode settings made on that dialog will override any mixed mode settings made on the HVAC model data tab for zones connected to that AHU.

See also the [Summary of Mixed mode modelling](#) for background information.

Mixed mode control zones

When using Detailed HVAC air systems a control zone is required to represent the zone conditions for all zones served by the AHU. The control zone conditions are fed into the HVAC mixed mode controller. The control zone is defined on the AHU dialog for Detailed HVAC.

Wind And Rain

Opening factor function of wind speed curve

Select a [Linear](#) or [Quadratic](#) performance curve that parameterizes the variation of opening factor as a function of outdoor wind speed. The output of this curve is multiplied by the opening factor of opening objects to give the final openness. This field only works with the AirflowNetwork (Calculated natural ventilation) opening objects.

Close windows and vents when raining

Indicates whether the rain indicator in the hourly weather data is used to shut off natural ventilation. This can help simulate conditions where one would normally close windows to avoid rain penetration in a space. Any possible rain getting into a space will not be counted as a zone load.

Maximum wind speed

The wind speed (in m/s or ft/min) above which natural ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid wind problems in a space (papers blowing around, etc).

Temperature Control

Minimum outdoor temperature

The outdoor temperature (in °C or °F) below which the entire mixed mode ventilation system is shut off when the control mode schedule value = 1 (Temperature). This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

Maximum outdoor temperature

The outdoor temperature (in °C or °F) above which the entire mixed mode ventilation system is shut off when the control mode schedule value = 1 (Temperature). This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

Note: When using Scheduled natural ventilation, the **Minimum/Maximum outdoor temperature** Mixed mode shut off values described above will override the settings made under the **Outdoor Temperature Limits** header.

Natural Ventilation

Temperature Control

Min outdoor temperature (°C): -100.0

Max outdoor temperature (°C): 100.0

These settings override the Outdoor Temperature Limits highlighted above

Enthalpy Control

Minimum outdoor enthalpy

The outdoor enthalpy (in J/kg or Btu/lb) below which the entire mixed mode ventilation system is shut off when the control mode schedule value = 2 (Enthalpy).

Maximum outdoor enthalpy

The outdoor enthalpy (in J/kg or Btu/lb) above which the entire mixed mode ventilation system is shut off when the control mode schedule value = 2 (Enthalpy).

Dewpoint Control

Minimum outdoor dewpoint

The outdoor dew point temperature (in °C or °F) below which the entire mixed mode ventilation system is shut off when the control mode schedule value = 3 (Dew point). This lower dew point temperature limit is intended to avoid dehumidifying a space.

Maximum outdoor dewpoint

The outdoor dew point temperature (in °C or °F) above which the entire mixed mode ventilation system is shut off when the control mode schedule value = 3 (Dew point). This upper dew point temperature limit is intended to avoid humidifying a space.

Advanced

Control mode schedule

This schedule determines whether or not for a given time the mixed mode ventilation control is to be applied. Schedule values equal to zero indicate no ventilation control, resulting in natural ventilation and HVAC system operation being performed based on their own controls. Schedule values equal to one denote temperature control for either cooling or heating, which is determined internally based on thermostat set point. The temperature control is restricted between the minimum and maximum outdoor temperatures provided in two additional input fields (below). Schedule values equal to two denote enthalpy control, which is restricted between minimum and maximum outdoor enthalpy values given in two additional input fields (below). Schedule values equal to three denote dew point control for either dehumidification or humidification. Schedule values equal to four represent outdoor ventilation air control.

Tip: The standard Calculated DesignBuilder natural ventilation options don't allow controls based on absolute outdoor air temperature, but it is possible to apply upper and/or lower outdoor air temperature limits for calculated natural ventilation through use of the Temperature control schedule mixed mode and the Mixed mode minimum and maximum temperatures.

Schedule value

0

1

2

3

(Calculated natural ventilation only)

Operation mode

No mixed mode control - HVAC and natural ventilation operate separately according to their own controls.

Temperature control for either cooling or heating - temperature control is restricted between minimum and maximum outdoor temperatures. When the outside air temperature falls below the minimum value or goes above the maximum value the openings are closed and the HVAC system operates. Enthalpy control, outside enthalpy is restricted between minimum and maximum outdoor enthalpy values. Dew point control, outside dew point temperature is restricted between minimum and maximum outdoor dew point values.

The minimum outdoor ventilation air for a given time in ac/h. The program calculates the natural (outdoor) ventilation in the controlled zone first and compares the amount of outdoor air brought by opening windows or doors and other small openings to this minimum value. If the amount of outdoor air from natural ventilation is less than the minimum value, the natural ventilation is shut off (i.e., the window or door openings are closed) and the HVAC system may operate if needed. Otherwise, the natural ventilation is on and the HVAC system is shut off. The amount of outdoor ventilation air entering the controlled zone is determined as air from outdoors and not from other adjacent zones. Therefore, this option is only applied to a zone having a window or door exposed to outdoors.

Minimum outdoor ventilation air schedule

The schedule is only used if [Ventilation Control Mode](#) = 4 (Outdoor Ventilation Air Control). This schedule determines the minimum outdoor ventilation air for a given time in the units of air change per hour (ac/h). The program calculates the natural (outdoor) ventilation in the controlled zone first and compares the amount of outdoor air introduced by opening windows or doors and other small openings to this minimum value. If the amount of outdoor air from natural ventilation is less than the minimum value, the natural ventilation is shut off (i.e., the window or door openings are closed) and the HVAC system may operate if needed. Otherwise, the natural ventilation is on and the HVAC system is shut off. The amount of outdoor ventilation air entering the controlled zone is determined as air from outdoors and not from other adjacent zones. Therefore, this option is only applied to a zone having a window or door exposed to outdoors.

AirflowNetwork control type schedule

This schedule is available when Calculated natural ventilation is set. It determines for a given simulation timestep how the openings respond to the mixed mode ventilation control. Schedule values equal to 0 indicate individual ventilation control based on the control requirements specified for each individual AirflowNetwork opening object. Schedule values equal to 1 denote "group" control. The opening objects exposed to outdoors in the controlled zone served by the primary [air loop](#) will be considered as a master to provide group control.

Simple airflow control type schedule

This schedule is available when the Scheduled natural ventilation model option is set. It works with ZoneVentilation:* and ZoneMixing objects only. This schedule determines for a given simulation timestep how the ZoneVentilation:* and ZoneMixing objects respond to the hybrid ventilation control when the hybrid ventilation control allows the objects to operate.

Schedule values equal to zero indicate the individual ventilation control based on the control requirements from their own objects. Schedule values equal to one denote group control. The ZoneVentilation:* and ZoneMixing objects in the zones served by the primary air loop are controlled by a single object, whose name is provided in the following input field.

Mixed Mode Cooling

In mixed-mode buildings, natural ventilation is the primary means of cooling, but when this is inadequate to provide comfort conditions, active cooling is introduced. The [Center for the Built Environment \(CBE\)](#) describes mixed mode buildings as follows.

Mixed-mode buildings employ a hybrid approach to space conditioning that combines operable windows and mechanical cooling. By taking advantage of the strengths of both systems, well-designed mixed-mode buildings can be more comfortable and use less energy. People who have more control over their indoor environments are typically more satisfied with temperature, air movement, and air quality. Mixed-mode buildings give occupants control while still allowing central control to keep the building near the comfort zone. The three basic categories of mixed-mode buildings describe how natural ventilation and mechanical cooling operate at different times and places. **Concurrent** systems allow open windows and air conditioning at the same time in the same place; **Changeover** systems allow them at different times in the same places; **Zoned** systems allow them at the same time in different places.

Mixed Mode Schematic from the [CBE website](#)

DesignBuilder can model all three types of mixed mode system.

1. **Concurrent** (*same space, same time*)
Concurrent mixed-mode operation is the most prevalent design strategy in practice today, in which the air-conditioning system and operable windows operate in the same space and at the same time. The HVAC system may serve as supplemental or “background” ventilation and cooling while occupants are free to open windows based on individual preference. Typical examples include open-plan office space with standard VAV air-conditioning systems and operable windows, where perhaps perimeter VAV zones may go to minimum air when sensor indicates that a window has been opened.
2. **Changeover** (*same space, different times*)
Changeover designs are becoming increasingly common, where the building switches between natural ventilation and air-conditioning modes on a seasonal or even daily basis. The building automation system may determine the mode of operating based on outdoor temperature, an occupancy sensor, a window (open or closed) sensor, or based on operator commands. Typical examples include individual offices with operable windows and personal air conditioning units that shut down for a given office any time a sensor indicates that a window has been opened; or a building envelope where automatic louvers open to provide natural ventilation when the HVAC system is in economizer mode, and then close when the system is in cooling or heating mode.
3. **Zoned** (*different spaces, same time*)
Zoned systems are also common, where different zones within the building have different conditioning strategies. Typical examples include naturally ventilated office buildings with operable windows and a ducted heating/ventilation system, or supplemental mechanical cooling provided only to conference rooms. For many mixed-mode buildings, operating conditions sometimes deviate somewhat from their original design intent (e.g., a building originally designed for seasonal changeover between air-conditioning and natural ventilation may, in practice, operate both systems concurrently).

Note: **Concurrent** and **Zoned** systems can be modelled simply by including natural ventilation with HVAC systems without using DesignBuilder mixed mode control. In DesignBuilder, the term “mixed mode” refers specifically to **Changeover** systems where the HVAC and the natural ventilation do not take place at the same time.

Mixed Mode Natural Ventilation Flow and Control

DesignBuilder supports mixed mode in all combinations of natural ventilation and HVAC model options.

The steps to setting up a change-over mixed mode model in DesignBuilder are:

1. Include active cooling and natural ventilation by switching on the [Natural ventilation](#) on and [Cooled](#) options on the HVAC tab.
2. Also, include mechanical ventilation if there is outside air introduced through the HVAC system. Note that Detailed HVAC AHUs allow [Mixed mode controls](#) to be defined to model optimal interaction between the natural ventilation system (Scheduled or Calculated) and the AHU.
3. Ensure that the [setpoints](#) for natural ventilation and cooling operation are correct. The natural ventilation (window/vent opening) setpoint should ideally be 2°C lower than the cooling setpoint to ensure maximum use of natural ventilation and to avoid the active cooling system being used unnecessarily and also 2°C higher than the heating .temperature. Typical values might be heating setpoint temperature = 21°C, natural ventilation setpoint temperature = 23°C, cooling setpoint temperature = 25°C. Heating should ideally be switched off in the summer to avoid unnecessary heating caused by natural ventilation overcooling the space.
4. See the [mixed mode](#) section on the HVAC help for detailed information on the data that can be set, including conditions that require windows and vents to be closed such as rain, wind and low outside air temperature.

Note: "Mixed mode" means the same as the term "Hybrid ventilation" used in the EnergyPlus documentation.

Mixed Mode Tutorial

This tutorial will help you get up to speed with running a changeover mixed mode natural ventilation study in a few easy steps.

In general, mixed mode controls can be used with either Calculated or Scheduled natural ventilation, Simple or Detailed HVAC. This tutorial demonstrates the process for the [Simple HVAC](#) and [Scheduled natural ventilation](#) model options as the easiest way to learn how to apply the mixed mode settings.

Step 1 - Create a base model

Start by creating a new file located in London Gatwick and add a building to the site with a simple rectangular block having dimensions 30m x 20m as shown below. Use default Model options.

In Simple HVAC mode, HVAC components are controlled using the Model data inputs on the Activity and HVAC tabs. The following steps describe the settings required on these tabs.

Step 2 – Make setpoint temperature settings on the Activity tab

To prevent simultaneous operation of the cooling and natural ventilation systems, the setpoint temperatures must be defined carefully. The recommended deadband between natural ventilation and heating/cooling is 2°C.

In this example, these setpoint temperatures should be entered as follows:

- [Heating setpoint](#): 21°C
- [Natural ventilation setpoint](#): 23°C
- [Cooling setpoint](#): 25°C.

The Activity tab, Environmental Control settings should now look like this:

Environmental Control		⌵
Heating Setpoint Temperatures		⌵
🔧 Heating (°C)	21	
🔧 Heating set back (°C)	12.0	
Cooling Setpoint Temperatures		⌵
🔧 Cooling (°C)	25	
🔧 Cooling set back (°C)	28.0	
Humidity Control		⌵
Ventilation Setpoint Temperatures		⌵
Natural Ventilation		⌵
☒ Indoor min temperature control		
Min temperature definition	1-By value	⌵
🔧 Min temperature (°C)	23	
☐ Indoor max temperature control		

Step 3 – Load the “Radiator heating, Boiler HW, Mixed mode Nat Vent, Local comfort cooling” HVAC Template

1. By default, DesignBuilder will load the “Fan Coil Unit” HVAC template in new models. For this example, you should change that by navigating to building level, clicking on the HVAC model data tab and loading the “Radiator heating, Boiler HW, Mixed mode Nat Vent, Local comfort cooling” HVAC Template.
2. Set the [maximum natural ventilation rate](#) to 3 ac/h.
3. Select the “Winter heating (Northern Hemisphere)” [Heating Operation Schedule](#) to ensure that heating is switched off in summer.

The HVAC tab should now look something like the screenshot below:

HVAC Template		▼
Template		Radiator heating, Boiler HW, Mixed mode Nat
Mechanical Ventilation		>>

Note that the heating, cooling, natural ventilation and mixed mode controls are all switched on.

Step 4 – Review the Mixed Mode Zone Equipment Settings

DesignBuilder provides a set of [Mixed Mode Zone Equipment](#) settings to allow various detailed aspects of the system to be controlled, as shown below.

Mixed Mode Zone Equipment	
☒ Mixed mode on	
Wind and Rain	
☐ Opening factor function wind speed c...	Opening Factor Function of Wind Speed Curve
☒ Close windows and vents when raining	
Max wind speed (m/s)	40.0
Temperature Control	
Min outdoor temperature (°C)	-100.0
Max outdoor temperature (°C)	100.0
Enthalpy Control	
Min outdoor enthalpy (J/kg)	20000
Max outdoor enthalpy (J/kg)	30000
Dew Point Control	
Min outdoor dew point temperature (°C)	15.0
Max outdoor dew point temperature (°C)	30.0
Advanced	
Control mode schedule	Mixed mode temperature control
Min outdoor ventilation air schedule	Minimum outdoor ventilation air schedule: Always 1 ac/
Scheduled airflow control type sched...	Simple Airflow Control Type Schedule: Always 0

For this tutorial you can use the defaults.

Step 5 – Reduce Lighting gains

To ensure that lighting internal gains are consistent with a modern naturally ventilated building, a more efficient system than the default “Reference” template should be loaded.

At building level, go to the Lighting tab and select the “LED with linear control” Lighting template.

The data on the Lighting tab should now be as below.

Lighting Template	
Template	LED with linear control
General Lighting	
☒ On	
Normalised power density (W/m2-100 lux)	2.5000
Schedule	Office_OpenOff_Light
Luminaire type	1-Suspended
Radiant fraction	0.420
Visible fraction	0.180
Convective fraction	0.400
Lighting Control	
☒ On	
Working plane height (m)	0.80
Control type	1-Linear
Min output fraction	0.100
Min input power fraction	0.100
Glare	>>
Lighting Area 1	>>
Lighting Area 2	>>

Step 6 – Reduce Solar gains

Similarly, to ensure that solar gains are kept in check and consistent with a modern naturally ventilated building, some window shading should be introduced.

At building level, go to the Openings tab and check the [Window shading](#) checkbox. By default, this will provide high reflectivity internal blinds for all windows.

The data on the Openings tab should now be as below.

Glazing Template	
Template	Project glazing template
External Windows	
Glazing type	Project external glazing
Layout	Preferred height 1.5m, 30% glazed
Dimensions	
Type	3-Preferred height
Window to wall %	30.00
Window height (m)	1.50
Window spacing (m)	5.00
Sill height (m)	0.80
Outside reveal depth (m)	0.000
Frame and Dividers	
Shading	
☒ Window shading	
Type	Blind with high reflectivity slats
Position	1-Inside
Control type	3-Schedule
Slat Angle Control	
Operation	
Schedule definition	1-Follow occupancy
☐ Local shading	

Step 7 - Run a simulation

We are now ready to run a test simulation.

1. Go to the Simulation screen and press the **Update** toolbar icon to open the [Simulation Calculation options](#) dialog.
2. Click on the "Summer typical week" Info panel link to load simulation dates for the typical summer week for this location.
3. Check the **Sub-hourly Output Interval for Reporting** to help you check the correct operation of the system.
4. On the [Options](#) tab, select the 6 [Timesteps per hour](#) option.
5. Press OK to run the Simulation.

Step 8 - Review Results

Select the **5-Sub-hourly** Interval in the Display options bottom left panel and review the results.

You should see graphs similar to those below.

The temperature graph shows that, during the working week, the inside air temperatures are controlled to be between 23 and 25°C during occupied periods. Temperatures are controlled to 23°C when natural ventilation is active, but when natural ventilation cannot meet the cooling demand, mechanical cooling is activated to maintain temperatures below 25°C.

The heat balance graph shows that cooling (blue line) and natural ventilation (green line) occur independently (never simultaneously) to meet the cooling load as required.

Earth Tubes

HVAC tab in model data

An earth tube is a long, underground metal or plastic pipe through which air is drawn. During the cooling season, as air travels through the pipe, it gives up some of its heat to the surrounding soil and enters the room as cooler air. Similarly, during heating season, as air travels through the pipe, it receives some of its heat from the soil and enters the room as warmer air. Simple earth tubes in EnergyPlus can be controlled by a schedule and through the specification of minimum, maximum, and delta temperatures as described below. As with infiltration and ventilation, the actual flow rate of air through the earth tube can be modified by the temperature difference between the inside and outside environment and the wind speed. See [equation below](#).

Note 1: Earth tubes are only available when using the [Scheduled natural ventilation](#) model option.

Note 2: Earth tube settings are used for heating and cooling design as well as in simulations.

CalcSoilSurfTemp – Auxiliary Programs Document

The **CalcSoilSurfTemp** program is simple and requires only two input fields : soil condition and soil surface condition in addition to a valid weather file. For soil condition, the user should select the number corresponding to the actual condition of the soil surrounding the earth tube from the four typical options to determine the thermal diffusivity and thermal conductivity of the surrounding soil. For soil surface conditions, the user should select the number corresponding to the actual condition of the ground surface above the earth tube from the eight following options:

- 1. BARE AND WET,
- 2. BARE AND MOIST,
- 3. BARE AND ARID,
- 4. BARE AND DRY,
- 5. COVERED AND WET,
- 6. COVERED AND MOIST,
- 7. COVERED AND ARID and
- 8. COVERED AND DRY.

This determines the absorption coefficient and the fraction of evaporation rate of the ground surface.

From this information and an analysis of the weather for the location selected, the **CalcSoilSurfTemp** program (ref. [Auxiliary Programs](#) document) calculates the three parameters described below- [Average soil surface temperature](#), [Amplitude of soil surface temperature](#) and [Phase constant of soil surface temperature](#). The full input description of an earth tube is given below.

Include earthtube

Check this option to include zone air delivery through earth tubes.

Outside air definition method

You can set the amount, timing and control of outside air delivery through the earth tubes in the same way as for Mechanical ventilation. Refer to the [Outside air](#) section for details of how this works.

The outside air definition data is used to calculate the the maximum amount of air mass flow rate of the earth tube expected at design conditions (E_{design} in the above equation in units of m³/s. The design value is modified by the schedule fraction (see next field) and user specified coefficients (last four fields).

Operation

Schedule

Select the [schedule](#) that modifies the maximum design volume flow rate (see previous field). The fraction in the schedules should vary between 0.0 and 1.0 and is referred to as F_{schedule} in the above equation.

Control

Minimum zone temperature when cooling

This is the indoor temperature (in °C or °F) below which the earth tube is shut off. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, earth tube is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then earth tube is automatically turned off.

Maximum zone temperature when heating

This is the indoor temperature (in °C or °F) above which the earth tube is shut off. This higher temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 20°C, earth tube is assumed to be available if the zone air temperature is below 20°C. If the zone air temperature rises above 20°C, then earth tube is automatically turned off.

Delta temperature

This is the temperature difference (in °C or °F) between the indoor and outdoor air dry-bulb temperatures below which the earth tube is shut off. This is to allow the earth tube to be stopped either if the temperature outside is too warm and could potentially heat the space or if the temperature outside is too cold and could potentially cool the space. For example, if the user specifies a delta temperature of 2°C, earth tube is assumed to be available if the temperature difference between indoor and outdoor temperature is at least 2°C. If the outside air dry-bulb temperature is less than 2°C cooler or warmer than the indoor dry-bulb temperature, then the earth tube is automatically turned off.

Fan Electric Consumption Configuration

Earth tube type

This alpha character string defines the type of earth tube as one of the following options:

- **1-Natural** which is assumed to be air movement/exchange that will not consume any fan energy or is the result of natural air flow through the tube and into the building. Values for fan pressure and efficiency for a natural flow earth tube are ignored. The conditions of the air entering the space are assumed to be equivalent to the air which is cooled or heated by passing along the pipe.
- **2-Intake** where values for fan pressure and efficiency define the fan electric consumption and an appropriate amount of fan heat is added to the air stream.
- **3-Exhaust** where values for fan pressure and efficiency define the fan electric consumption.

Fan pressure rise

This is the pressure rise experienced across the fan (in Pascals (N/m²) or psi). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan. This value is only entered for fan-driven earth tubes.

Fan total efficiency

This is the total fan efficiency (a decimal number between 0.0 and 1.0). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan. This value is only entered for fan-driven earth tubes.

Pipe Specifications

Pipe radius

This is the radius of the earth tube/pipe (in m or ft). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. If the pipe has non-circular cross section, user can use the concept of hydraulic diameter as follows.

$$D = 4 \cdot A / \text{Perimeter}$$

However, since this field requires the pipe radius, hydraulic diameter should be divided by two.

Pipe thickness

This is the thickness of the pipe wall (in m or ft). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

Pipe length

This is the total length of the pipe (in m or ft). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. As the length of the pipe becomes longer, the amount of the heat transfer becomes larger.

Pipe thermal conductivity

This is the thermal conductivity of the pipe (in W/mC or Btu-in/h-ft²-F). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

Pipe depth under ground surface

This is the depth of the pipe under the ground surface (in m or ft). This plays a role in determining the temperature of the soil surrounding the pipe.

Soil Heat Transfer Calculations

Soil condition

This alpha character string defines the actual condition of the soil surrounding the earth tube and can be one of any of the following options:

- **1-Heavy and Saturated,**
- **2-Heavy and Damp,**
- **3-Heavy and dry or**
- **4-Light and Dry.**

This determines the thermal diffusivity and thermal conductivity of the surrounding soil, which play a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

Average soil surface temperature

This is the annual average soil surface temperature straight above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This field should be calculated in advance using the separate **CalcSoilSurfTemp** program.

Amplitude of soil surface temperature

This is the amplitude of soil surface temperature above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This is the difference between the maximum and minimum soil surface temperature for the whole year divided by two. This field should be calculated in advance using the separate **CalcSoilSurfTemp** program. It is a Delta temperature value.

Phase constant of soil surface temperature

This is the phase constant of the soil surface temperature straight above the earth tube, which play a role in determining the temperature of the soil surrounding the pipe at particular time. This is the time elapsed from the beginning of the year until the soil surface temperature reaches the minimum value of the year. This field should be calculated in advance using the separate **CalcSoilSurfTemp** program.

Flow Term Coefficients

The basic equation used to calculate air flow rate of earth tube in EnergyPlus is:

$$\text{EarthTubeFlowRate} = E_{\text{design}} F_{\text{schedule}} (A + B \cdot \text{abs}(T_{\text{zoneair}} - T_{\text{odb}}) + C \cdot \text{WindSpeed} + D \cdot \text{WindSpeed}^2)$$

Constant term flow coefficient

This number is the “A” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

Temperature term flow coefficient

This number is the “B” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

Velocity term flow coefficient

This number is the “C” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

Velocity squared term flow coefficient

This number is the “D” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s²/m².

Outputs

Note: Airflow introduced into zones by Earth tubes is included in the **Mech Vent + Nat Vent + Infiltration** ac/h output. Also the heating/cooling effect of Earth tubes on the zone is included in the **Zone Vent** heat balance output. If you would like to see further details on the impact of the Earth tubes in your results then you should include one or more of the output variables below to an [external idf file](#), "include" it in the main IDF file generated by DesignBuilder and view results in the [Results Viewer](#).

Current Earth Tube output variables:

- HVAC,Sum,Earth Tube Zone Sensible Cooling Energy [J]
- HVAC,Average,Earth Tube Zone Sensible Cooling Rate [W]
- HVAC,Sum,Earth Tube Zone Sensible Heating Energy [J]
- HVAC,Average,Earth Tube Zone Sensible Heating Rate [W]
- HVAC,Sum,Earth Tube Air Flow Volume [m³]
- HVAC,Average,Earth Tube Air Volume Flow Rate [m³/s]
- HVAC,Sum,Earth Tube Air Flow Mass [kg]
- HVAC,Average,Earth Tube Air Mass Flow Rate [kg/s]
- HVAC,Sum,Earth Tube Fan Electric Energy [J]
- HVAC,Average,Earth Tube Fan Electric Power [W]
- HVAC,Average,Earth Tube Zone Inlet Air Temperature [C]
- HVAC,Average,Earth Tube Ground Interface Temperature [C]
- HVAC,Average,Earth Tube Outdoor Air Heat Transfer Rate [W]

Earth Tube Zone Sensible Cooling Energy [J]

Earth Tube Zone Sensible Cooling Rate [W]

These are the energy and rate associated with the zone cooling provided by the air from the earth tube. This occurs when the earth tube outlet air temperature is less than zone air temperature.

Earth Tube Zone Sensible Heating Energy [J]

Earth Tube Zone Sensible Heating Rate [W]

These are the energy and rate associated with the zone heating provided by the air from the earth tube. This occurs when the earth tube outlet air temperature is greater than the zone air temperature.

Earth Tube Air Flow Volume [m³]

The volume flow of air through the earth tube.

Earth Tube Air Volume Flow Rate [m³/s]

The volume flow rate of air through the earth tube.

Earth Tube Air Flow Mass [kg]

The mass flow of air through the earth tube.

Earth Tube Air Mass Flow Rate [kg/s]

The mass flow rate of air through the earth tube.

Earth Tube Fan Electric Energy [J]

Earth Tube Fan Electric Power [W]

These are the fan electricity consumption and power for intake or exhaust earth tube types.

Earth Tube Zone Inlet Air Temperature [C]

This is the temperature of the air entering the zone after passing through the earth tube [C]. This temperature includes the cooling or heating of outdoor air as it passes along the pipe. When intake fan assist is used, then the additional heat due to the fan is included in the inlet air temperature.

Earth Tube Ground Interface Temperature [C]

This is the average temperature of the ground along the outer surface of the earth tube [C].

Earth Tube Outdoor Air Heat Transfer Rate [W]

This is the rate of heat transfer from the earth tube to the outdoor air [W]. Positive values indicate the rate at which outdoor air is preheated; negative values indicate the rate of precooling.

Domestic Hot Water

[HVAC tab](#) in model data Simple HVAC

The effect of hot water consumption (hot water taps, showers etc) on building energy use can be included in your thermal model by switching on [DHW](#) on the HVAC tab.

When using Simple HVAC, Domestic Hot Water (DHW) is modelled in DesignBuilder by using hot water consumption rates based on the [activity](#) in each zone. DHW hot water consumption is defined on the [Activity tab](#) and the definition of the hot water generating equipment is described below) is defined on the [HVAC tab](#).

Type

Three types of DHW are available:

- **1-Boiler** - heat is supplied by the same boiler used for heating the building
- **2-Gas** - gas-fired hot water system
- **3-Electric** - electric immersion heater

Delivery hot water temperature

The temperature of the water supplied to the taps.

Mains supply temperature

The average temperature of the water delivered to the building over the year. This can be approximated to the annual average outside air temperature.

Operation

The DHW Operation schedule defines the timing of the hot water draw off.

The [DHW consumption rate](#) is defined on the Activity tab in l/m2-day (gal/ft2-day in IP units) but this needs processing before being passed into E+ which requires max DHW flow in m3/s. To do this DesignBuilder needs to use the concept of number of operation hours per day (or 'Typical hours per day') based on this operation schedule.

When a [Compact schedule](#) is used to define DHW operation, DesignBuilder calculates the 'Typical hours per day' based on the day in the year which has the most operation hours. Fractional hours operation are included as fractions. A 30 minute timestep through the year is used to perform this calculation.

Example 'Typical hours per day' calculation for Compact schedules

Schedule: Compact,
Example Occupancy,
Fraction,
Through: 31 Dec,
For: Weekdays SummerDesignDay,
Until: 08:00, 1,
Until: 16:00, 0,
Until: 18:00, 0.5,
Until: 24:00, 1,
For: Weekends,
Until: 08:00, 1,
Until: 20:00, 0,
Until: 24:00, 1,
For: AllOtherDays,
Until: 08:00, 1,
Until: 16:00, 0,
Until: 18:00, 0.5,
Until: 24:00, 1;

For this schedule, the Weekdays give the most operation hours:

Until: 08:00, 1,
Until: 16:00, 0,
Until: 18:00, 0.5,
Until: 24:00, 1,

In this case 'Typical hours per day' would be calculated as:

$8 * 1 + 8 * 0 + 2 * 0.5 + 6 * 1 = 15 \text{ hours.}$

When 7/12 schedules are used the typical occupancy hours per day is determined from **January/Monday** data.

When typical workday schedules are used, this is simply the number of hours occupied during the working day.

The DHW volumetric consumption rate supplied to EnergyPlus is calculated as:

$$\text{DHW (m3/s)} = \text{DHW (l/m2-day)} \times 0.001 \times \text{m2} / (\text{Typical hours per day} \times 3600)$$

Note: the zone DHW operation schedule is also used in Detailed HVAC when the default **1-Simple HVAC Detailed HVAC Activity data** setting is made.

DHW Type

A range of DHW types can be selected but note that different types of DHW system do not affect results in EnergyPlus simulations, apart from **1- Same as HVAC** which causes heating CoP and fuel to be taken from the heating system. Other options all give the same results.

- 1- Same as HVAC
- 2- Dedicated DHW boiler
- 3- Stand alone water heater
- 4- Instantaneous DHW only
- 5- Instantaneous Combi
- 6- Direct (or off-peak) electricity
- 7- Heat pump

Air Temperature Distribution

[HVAC tab](#) in model data

By default EnergyPlus assumes that air temperature within a zone is completely uniform (i.e. the air is fully mixed). However a number of other modelling options are provided to account for non-uniform room air temperatures that may occur within the interior air volume of a zone.

Although there are many types of analyses (comfort, indoor air quality, etc.) that might benefit from localized modelling of how room air varies across space, only the temperature distribution of room air within the zone is currently addressed in EnergyPlus. This allows surface heat transfer and air system heat balance calculations to be made taking into account natural thermal stratification of air and different types of intentional air distribution designs such as under-floor and side-wall displacement ventilation that purport to extract room air at higher-than-mean temperatures. Note that EnergyPlus does not have completely general methods of modelling room air that are applicable to every conceivable type of airflow that might occur in a zone. Such models (e.g. RANS-CFD) are too computationally expensive to use with EnergyPlus for the foreseeable future. The models that are available in EnergyPlus offer only limited modelling capabilities for select room airflow configurations. Also note that because the complete mixing model for room air has long been the standard in building energy simulation, there is not currently a consensus on how to best model non-uniform air temperatures in buildings. Therefore, it is up to the user to have a good understanding of when, where, and how to apply the room air models available in EnergyPlus. The rest of this section provides some guidance in the way of examples and further discussion of the models available in EnergyPlus.

The following room air temperature distribution models are provided:

- **1-Mixed** the default option where the air temperature is modelled as being uniform through the zone.
- **2-Dynamic gradient** which allows air temperature stratification within a zone to be modelled by setting up a temperature gradient which varies dynamically depending on any of: outside temperature, inside temperature, inside-outside temperature difference, heating load or cooling load.
- **3-Three node displacement ventilation** which uses 3 nodes to model spaces that are served by a low velocity floor-level displacement ventilation air distribution system and the dominant sources of heat gain are from people and other localized sources located in the occupied part of the room.
- **4-Underfloor air distribution interior** which uses upper and a lower sub-zone nodes to model interior spaces that are served by an underfloor air distribution system and the dominant sources of heat gain are from people, equipment, and other localized sources located in the occupied part of the room.
- **5-Underfloor air distribution exterior** which uses upper and a lower sub-zone nodes to model exterior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room, as well as convective gain coming from a warm window.

Air Temperature Distribution - Dynamic Gradient

[HVAC tab in model data](#)

The **Dynamic Gradient** Air Distribution model data allows you to model stratification within a zone by setting up a temperature gradient which varies dynamically depending on:

- Outside temperature.
- Inside temperature.
- Inside-outside temperature difference.
- Heating load.
- Cooling load.

Gradient interpolation mode

This field specifies how the program will vary between the two gradients. Select one of the following keywords to choose the simulation data used to scale: 'Outdoor Environment Drybulb Temperature', 'Zone Drybulb Temperature', 'Delta Outdoor and Zone Temperature', 'Sensible Cooling Load', and 'Sensible Heating Load'. These are explained in detail below. All of these options have several things in common. They are essentially hard-coded. There is no support for a general method. The interpolation scheme is based on some variable that might reasonably be expected to correlate with gradient changes. This variable's current value is used to continually adjust the value of the vertical gradient for room air temperature.

- **1-Outside temperature.** This option directs the program to interpolate between upper and lower values of the vertical gradient based on the outdoor air temperature. If the outdoor temperature exceeds the upper limit set under the **Upper Conditions** header, then the gradient entered in the **Upper Conditions > Temperature gradient** field is used. Similarly if the outdoor air temperature is below the value set in the **Lower Conditions > Temperature** field, then the gradient entered in the **Lower Conditions > Temperature gradient** is used. For outdoor temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.
- **2-Inside temperature.** This option directs the program to interpolate between upper and lower values of the vertical gradient based on the mean zone air temperature. If the mean zone air temperature exceeds the upper limit set under the **Upper Conditions** header, then the gradient entered in the **Upper Conditions > Temperature gradient** field is used. Similarly if the mean zone air temperature is below the value set in the **Lower Conditions > Temperature** field, then the gradient entered in the **Lower Conditions > Temperature gradient** is used. For mean zone air temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.
- **3-Inside outside Delta T.** This option directs the program to interpolate between upper and lower values of the vertical gradient based on the difference between the outdoor environment and the mean zone air temperature. If the temperature difference exceeds the upper limit set under the **Upper Conditions** header, then the gradient entered in the **Upper Conditions > Temperature gradient** field is used. Similarly if the temperature difference is below the **Lower Conditions > Temperature** field, then the gradient entered in the **Lower Conditions > Temperature gradient** is used. For temperature differences that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.
- **4-Sensible cooling load.** This option directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible cooling load. If the cooling load exceeds the upper limit set under the **Upper Conditions** header, then the gradient entered in the **Upper Conditions > Temperature gradient** field is used. Similarly if the cooling load is below the value set in the **Lower Conditions > Heat rate** field, then the gradient entered in the **Lower Conditions > Temperature gradient** is used. For cooling loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.
- **5-Sensible heating load.** This option directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible heating load. If the heating load exceeds the upper limit set under the **Upper Conditions** header, then the gradient entered in the **Upper Conditions > Temperature gradient** field is used. Similarly if the heating load is below the value set in the **Lower Conditions > Heat rate** field, then the gradient entered in the **Lower Conditions > Temperature gradient** is used. For heating loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

Upper Conditions

Temperature

This field is used to enter the upper bound on temperature values (in °C or °F). It is required for the interpolation modes based on temperature.

Heat rate

This field is used to enter the upper bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in W).

Temperature gradient

This field specifies the gradient, or slope, of temperature changes in the vertical direction (in °C/m or °F/ft) when the selected temperature or heat load is at or above the upper condition.

Lower Conditions

Temperature

This field is used to enter the lower bound on temperature values (in °C or °F). It is required for the interpolation modes based on temperature.

Heat rate

This field is used to enter the lower bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in W).

Temperature gradient

This field specifies the gradient, or slope, of temperature changes in the vertical direction (in °C/m or °F/ft) when the selected temperature or heat load is at or below the lower condition.

Operation.

Operation schedule

The operation schedule defines the times when air temperature distribution is to be calculated. When the value of the schedule is 1, the distribution calculations take place, when the value is 0, the zone air temperature is fully mixed.

Heights

Thermostat height

Thermostat height specifies the distance above the floor where the thermostat for HVAC control is situated. This height is used by the model to determine the thermostat temperature relative to the mean air temperature by applying the gradient.

Return air height

Return air height specifies the distance above the floor where the air leaves the zone and returns to the air system. This height is used by the model to determine the return air temperature relative to the mean air temperature by applying the gradient.

Range of applicability

The air temperature distribution within the zone is used as follows:

1. To calculate boundary conditions for conduction through surfaces (walls, roofs, glazing etc).
2. To include the effects of extracting relatively warmer air at the ceiling level when using Detailed HVAC.
3. To include the vertical position of the thermostat sensor for HVAC control.

How It Works

Changing the Distribution mode to **2-Dynamic gradient** reveals the air temperature distribution data. By default the Interpolation mode is **3-Inside-outside DeltaT**. This means that the temperature gradient within the space is modelled as varying according to the inside-outside temperature difference. The Upper conditions define the most extreme temperature gradient, typically under design conditions. By default, the upper temperature difference is 10 °C and the corresponding temperature gradient is 4 °C/m. This means that when the temperature difference between inside and outside is 10 °C or more the internal temperature gradient is 4 °C/m. The Lower conditions data shows that when the temperature difference between inside and outside is zero there is no temperature gradient, i.e. the air is fully mixed. EnergyPlus calculates the temperature gradient for other inside-outside temperature differences by linear interpolation. The calculation is similar for the other interpolation modes but is instead based on outside temperature, inside temperature, heating or cooling load.

Limitations

The air temperature distribution mechanism does not include:

1. The effects of extracting relatively warmer air at the ceiling level when using Scheduled and Calculated natural ventilation.
2. The vertical position of the sensor for ventilation control.

Air Temperature Distribution - Three Node Displacement Ventilation

[HVAC tab in model data](#)

This model is applicable to spaces that are served by a low velocity floor-level displacement ventilation air distribution system. Furthermore, the dominant sources of heat gain should be from people and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts three temperatures in the room:

- A foot level temperature (T_{FLOOR}). The floor region is 0.2 meters deep and T_{FLOOR} represents the temperature at the mid-point of the region.
- An occupied sub-zone temperature (T_{OC}), representing the temperature in the region between the floor layer and the upper, mixed layer.
- An upper node representing the mixed-layer/outflow temperature (T_{MX}) essential for overall energy budget calculations and for modelling comfort effects of the upper layer temperature.

The following fields are used to define the **Three node displacement ventilation** room air temperature distribution.

Gain distribution schedule

Select the schedule defining the fractions of the convective portion of the internal gains in the occupied subzone that remain in the occupied subzone. The remainder of the convective portion of the internal gains in the occupied subzone enters the plumes and is carried to the upper subzone. The types of internal gains that are assumed to be located in the occupied subzone are:

- people
- task lights
- electric equipment
- gas equipment
- hot water equipment
- steam equipment
- other equipment

- baseboard heat

Types of internal gains that are assumed to be in the upper subzone are:

- general lights
- tubular daylighting devices
- high temperature radiant heaters

The schedule values should be between 0 and 1. A value of 1 means that all the convection gains from equipment, task lights and people are dispersed in the lower occupied subzone. Conversely a value of 0 puts all the lower subzone convective gains into the plumes rising into the upper well-mixed subzone.

Number of plumes per occupant

This field specifies number of plumes per occupant. Plumes are associated with localized sources of convective heat gain from people and equipment. For example, a value of 2.0 would be used if each occupant has a computer that generates a separate plume that does not merge with the plume from the occupant in the lower, occupied, subzone.

Thermostat height

This field is the height (in m or ft) of the thermostat/temperature control sensor above the floor.

Comfort height

The height (in m or ft) above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1m.

Advanced

Temperature difference threshold for reporting

This field specifies a minimum temperature difference between the upper mixed subzone and the occupied subzone that will be used to trigger whether or not the displacement ventilation auxiliary outputs will be calculated. These outputs are Room Air Zone Transition Height, Room Air Zone Recommended Minimum Flow Fraction, Room Air Zone Average Temperature Gradient and Room Air Zone Maximum Temperature Gradient. They are set to negative values when the temperature difference is less than the threshold and the output Room Air Zone Is Mixed Status is set to 1.

The value should be greater than or equal to zero and is in units of Delta °C or Delta °F. The default value is 0.4°C.

Air Temperature Distribution - Under Floor Interior

[HVAC tab in model data](#)

This model is applicable to interior spaces that are served by an underfloor air distribution (UFAD) system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain.

The model predicts two temperatures in the room:

- An occupied subzone temperature (T_{oc}), representing the temperature in the region between the floor and the boundary of the upper subzone.
- An upper subzone temperature (T_{mx}) essential for overall energy budget calculations and for modelling comfort effects of the upper layer temperature.

The following fields are used to define the [Under Floor Air Distribution \(UFAD\) Interior](#) data.

Number of diffusers

The total number of diffusers in this zone. This field can be allowed to **Autocalculate** (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft². The default for this field is **Autocalculate**.

Power per plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 W. However, the model assumes an “equivalent” plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should normally be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is **Autocalculate**.

Design effective area of diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m², for variable area diffusers 0.035 m², for horizontal swirl diffusers 0.006 m², and for linear bar grilles 0.03 m². The default is **Autocalculate**.

Diffuser slot angle from vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The default is **Autocalculate** in which case the setting depends on the diffuser type: for swirl diffusers it is 28°, for variable area diffusers 45°, for DV diffusers 73°, and for linear bar grilles 15°.

Diffuser type

The choices for this alpha field are:

- **1-Swirl** - a fixed area diffuser
- **2-Variable area** maintain an approximately constant exit velocity
- **3-Horizontal swirl** - fixed area diffuser
- **4-Linear bar grille** - fixed area diffusers normally used in exterior zones.
- **5-Custom** - the coefficients A to E should be entered to define the performance of the diffuser (below) rather than let the program set the coefficients based on diffuser type.

The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is **1-Swirl**.

Custom Diffuser Coefficients

When the diffuser type is set to **5-Custom** the coefficients A to E should be entered to define the performance of the diffuser. The coefficients are used in the equation:

$$K_c = A * \text{Gamma}^B + C + D * \text{Gamma} + E * \text{Gamma}^2.$$

Gamma is a variable that characterizes the amount of stratification in a UFAD zone. K_c is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type.

Coefficient A

The coefficient A in the above formula.

Coefficient B

The coefficient B in the above formula.

Coefficient C

The coefficient C in the above formula.

Coefficient D

The coefficient D in the above formula.

Coefficient E

The coefficient E in the above formula.

Height Settings

Thermostat height

This field is the height (in m or ft) of the thermostat/temperature control sensor above the floor. The default is 1.2m.

Comfort height

The height (in m or ft) above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1m.

Set transition height

If you would like to define the Transition height (below) then check this check box.

Transition height

An optional field to allow the transition height (in m or ft above floor) to be defined rather than have the program calculate it. The default is 1.7m.

Advanced

Temperature difference threshold for reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are Room Air Zone Transition Height and Room Air Zone Average Temperature Gradient. They are set to zero when the temperature difference is less than the threshold and the output Room Air Zone Is Mixed Status is set to 1.

The value should be greater than or equal to zero and is in units of Delta °C or Delta °F. The default value is 0.4°C.

Air Temperature Distribution - Under Floor Exterior

[HVAC tab in model data](#)

This model is applicable to exterior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room, as well as convective gain coming from a warm window. The model predicts two temperatures in the room:

- An occupied subzone temperature (T_{oc}), representing the temperature in the region between the floor and the boundary of the upper subzone..
- An upper subzone temperature (T_{mx}) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define the **Under Floor Air Distribution (UFAD) Exterior** data.

Number of diffusers

The total number of diffusers in this zone. This field can allowed to **Autocalculate** (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft². The default for this field is **Autocalculate**.

Power per plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 W. However, the model assumes an “equivalent” plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should normally be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is **Autocalculate**.

Design effective area of diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m², for variable area diffusers 0.035 m², for horizontal swirl diffusers 0.006 m², and for linear bar grilles 0.03 m². The default is **Autocalculate**..

Diffuser slot angle from vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The default is **Autocalculate** in which case the setting depends on the diffuser type: for swirl diffusers it is 28°, for variable area diffusers 45°, for DV diffusers 73°, and for linear bar grilles 15°.

Diffuser type

The choices for this alpha field are:

- **1-Swirl** - a fixed area diffuser
- **2-Variable area** maintain an approximately constant exit velocity
- **3-Horizontal swirl** - fixed area diffuser
- **4-Linear bar grille** - fixed area diffusers normally used in exterior zones.
- **5-Custom** - the coefficients A to E should be entered to define the performance of the diffuser (below) rather than let the program set the coefficients based on diffuser type.

The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is **1-Swirl**.

Custom Diffuser Coefficients

When the diffuser type is set to **5-Custom** the coefficients A to E should be entered to define the performance of the diffuser. The coefficients are used in the equation:

$$K_c = A * \text{Gamma}^{**}B + C + D * \text{Gamma} + E * \text{Gamma}^{**}2.$$

Gamma is a variable that characterizes the amount of stratification in a UFAD zone. K_c is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type.

Coefficient A

The coefficient A in the above formula.

Coefficient B

The coefficient B in the above formula.

Coefficient C

The coefficient C in the above formula.

Coefficient D

The coefficient D in the above formula.

Coefficient E

The coefficient E in the above formula.

Height Settings

Thermostat height

This field is the height (in m or ft) of the thermostat/temperature control sensor above the floor. The default is 1.2m.

Comfort height

The height (in m or ft) above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1m.

Set transition height

If you would like to define the Transition height (below) then check this check box.

Transition height

An optional field to allow the transition height (in m or ft above floor) to be defined rather than have the program calculate it. The default is 1.7m.

Advanced

Temperature difference threshold for reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are Room Air Zone Transition Height and Room Air Zone Average Temperature Gradient. They are set to zero when the temperature difference is less than the threshold and the output Room Air Zone Is Mixed Status is set to 1.

The value should be greater than or equal to zero and is in units of Delta °C or Delta °F. The default value is 0.4°C.

HVAC Cost

Air temperature distribution tab on [HVAC Templates](#) Dialog.

The HVAC cost is calculated zone by zone by multiplying the zone floor area by the cost per floor area (GIFA) for the zone on the HVAC tab. This data will normally be loaded from the HVAC template to ensure that HVAC performance and cost data are consistent.

This cost should include any contributions to the total cost of the building HVAC system from plant components and not only the components within the particular zone.

Note: This data is used for both Simple and Detailed HVAC for costing purposes.

Tip: The [Cost data](#) help topic provides an overview of the places in DesignBuilder where costs are entered.

Cost per area

Enter the total cost per floor area (GIFA) for the HVAC system. This data is used when the [HVAC calculation method](#) is set to **1-Cost per area**.

HVAC cost per cooling load

Enter the indicative cost of the cooling element of this HVAC system type (in GBP/kW). This data is used when the [HVAC calculation method](#) is set to **2-Cost per capacity** option and the cost for each zone is calculated based on its HVAC system capacity.

HVAC cost per heating load

Enter the indicative cost of the heating element of this HVAC system type (in GBP/kW). This data is used when the [HVAC calculation method](#) is set to **2-Cost per capacity** option and the cost for each zone is calculated based on its HVAC system capacity.

Environmental Impact Factors

[HVAC tab in model data](#)

The Environmental Impact Factors data contains additional information that is not individually specified in the [Fuel emission factors](#) data. Source to Site conversion factors for District Heating, District Cooling and Steam are entered in this object.

This data can only be accessed when using the [Detailed HVAC](#) model option. It is available at building level only.

District heating efficiency

The District heating efficiency value is used to convert the district (purchased) heating energy to Natural Gas for the environmental impact calculation. The efficiency is a number between 0 and 1 and divided into the district heating energy and the default is 0.3.

District cooling COP

The District cooling COP value is used to convert the district (purchased) cooling energy to electricity for the environmental impact calculation. The Coefficient of Performance (COP) is a number greater than 0 and divided into the purchased cooling energy with a default of 3.0.

Steam conversion efficiency

The Steam conversion efficiency is used to convert the Steam usage to Natural Gas for the environmental impact calculation. The efficiency is a number between 0 and 1 and divided into the purchased heating energy and the default is 0.25.

Total carbon equivalent emission factor from N2O

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. N2O (nitrous oxide) can be produced by some Fuel Types and has a default of carbon equivalent emission factor of 80.7272 kg C/kg N2O.

Total carbon equivalent emission factor from CH4

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. CH4 (methane) can be produced by all Fuel Types and has a default carbon equivalent emission factor of 6.2727 kg C/kg CH4.

Total carbon equivalent emission factor from CO2

The Intergovernmental Panel on Climate Change has studied the effects on the relative radiative forcing effects of various greenhouse gases. This effect, called Global Warming Potential (GWP), is described in terms of the Carbon Equivalent of a particular greenhouse gas. CO2 (carbon dioxide) can be produced by all Fuel Types and has a default carbon equivalent emission factor of 0.2727 kg C/kg CO2.

On Site Electricity Generation

Generation tab in model data

EnergyPlus provides a range of different on site electricity generation options and these are coordinated during the simulation through use of one or more [Electric load centres](#). These define how the various generation components are operated and coordinated together.

DesignBuilder currently supports various types of electric generators PV, BIPV, Wind, Internal combustion engine and micro turbine.

Settings for electricity generation are made at Building level on the **Generation** tab under the **On Site Electricity Generation** header.

Include electric load centres

Check the **Include electric load centres** checkbox to model electric generation.

Number of electric load centres

Set the number of electric load centres to be modelled. Choose a value from 1 to 30.

Load centre 1, 2, 3 etc

Create and select a load centre for each of the load centres from 1 to the **Number of electric load centres** defined.

Note: The order of the Electric load centre objects selected on the Generation tab is significant and is used to structure how generators are dispatched, the first load centres and generators being managed before the later ones.

Note: Each Load centre can only be selected once. If you have multiple similar Load centres, each must be defined separately. For example, this configuration is allowed:

On Site Electricity Generation

☒ Include electric load centres

Number of electric load centres

How To Model Photovoltaic (PV) Systems

How To Model A Standalone PV Solar System - Summary

You can include PV panels in your model by following the instructions below.

1. Position and size PV panels by following instructions in the [Adding Solar Collectors](#) topic.
2. To access the properties of the PV panel navigate to the solar collector object by double-clicking on the graphical object from building level or single-click on the solar collector item in the Navigator.
3. Once at the Solar collector object, define the performance and other panel properties on the **Constructions** tab under the [Solar Collector](#) header.
4. Define the electric side of the PV system at building level on the **Generation** tab under the [On Site Electricity Generation](#) header:
 - a. Check the **Include electric load centres** check box.
 - b. Add an [Electric load centre](#) and edit the details of the system.
 - c. Select one of [the DC buss types](#).
 - d. Select the [Inverter](#) type.
 - e. If using electrical storage define the [Storage](#) type.
 - f. Select the [building solar collector](#) on the [Generator list](#) tab.
 - g. Make sure that, having defined a new [Electric load centre](#), the correct one is selected on the **Generation** tab.
5. When the simulation is finished you can view solar PV contributions on the **Analysis** and **Summary** tabs:

Electric Loads Satisfied

	Electricity [kWh]	Percent Electricity [%]
Fuel-Fired Power Generation	0.00	0.00

How To Model A Building Integrated PV (BIPV) Solar System - Summary

You can include BIPV systems in your model by following the instructions below.

1. Define one or more constructions and/or glazing systems using the **Building Integrated Photovoltaics** category (for constructions) or the **Glazing Integrated Photovoltaics** category for glazing.
2. Define the properties of the PV system on the [Construction/glazing](#) dialog under the definition of the outermost layer.
3. Apply the BIPV systems by selecting the corresponding BIPV construction and/or glazing components on the relevant surfaces. Note that in larger models, the "Model Data Grid View (MDGV)" on page 658 is an efficient way to apply BIPV constructions to particular façades based on surface slope, orientation, tag etc.
4. Define the electric side of the PV system at building level on the **Generation** tab under the [On Site Electricity Generation](#) header:
 - a. Check the **Include electric load centres** check box.
 - b. Add an [Electric load centre](#) and edit the details of the system.
 - c. Select one of [the DC buss types](#).
 - d. Select the [Inverter](#) type.
 - e. If using electrical storage define the [Storage](#) type.
 - f. On the [Generator list](#) tab, select the DC generator type to be one of **2-Construction with BIPV** or **3-Glazing with BIPV**
 - g. Select under that the BIPV construction or glazing covered by that generator. Create one generator per BIPV construction and glazing used in the model. Any BIPV constructions not selected here will not generate electricity.
 - h. Make sure that, having defined a new [Electric load centre](#), the correct one is selected on the Generation tab.
5. When the simulation is finished you can view solar PV contributions on the Analysis and Summary tabs:

Electric Load Centre

Electric load centres are components used to include on-site electricity generators in a simulation. The electric load centre dispatches generators according to operation schemes and tracks and reports the amount of electricity generated and purchased. When using on-site generators, the program provides a “net” report where the total electricity used is reduced by the amount generated on site. Electrical demand tracking is done by the internal or custom meters used by EnergyPlus for reporting. The dispatching of different generators is based on expectations based on their nominal/rated electric power output. If the current conditions are such that the generator model determines that generation was higher or lower, then the results of the dispatch may differ from expectations.

Up to 5 different Electric load centre components can be included in simulations by making selections on the [On Site Electricity Generation](#) tab. A great deal of flexibility is available by mixing different load centres and operating schemes. If multiple load centres are used, the supervisory control will dispatch generators sequentially across the load centres.

Electric load centres effectively serve as a “load” to the generators and “supply” power to the rest of the building. The internal meters used by EnergyPlus for reporting do all of the demand tracking. The electric load centre manager sums all of the building and system electric loads and provides operating schemes for the generators. What is not provided by the on-site generation equipment, and electric storage units if specified, is met by (purchasing) off-site electricity.

The electricity produced from generators such as photovoltaic arrays, wind turbines and cogeneration is reported in the electricity produced output variable and will reduce the demand that the generators will try to meet for that timestep.

Load centres can include both power conditioning and [storage](#). Separate [inverter](#) models are used to condition DC power from [photovoltaic panels](#) and [BIPV systems](#) into AC power for the building and utility. Load centres serving PV need to be specified with a direct current (d.c.) buss. The other generators may have inverters inside the devices but these are already embedded in the generator models.

General

Name

This alpha field contains the identifying name for the electric load centre.

Generator operation scheme type

Select the type of operating scheme for the generator set. The various operating schemes affect how loads are dispatched to the generators, in effect telling the generators whether or not to run and requesting power levels. The available operating schemes are:

- **1-Base load** operates the generators at their rated (requested) electric power output when the generator is scheduled on. This scheme requests all generators scheduled on (available) to operate, even if the amount of electric power generated exceeds the total facility electric power demand.
- **2-Demand limit** - limits the amount of purchased electrical from the utility to an amount specified. The Demand limit scheme tries to have the generators meet all of the demand above the purchased electric limit.
- **3-Track electrical** tries to have the generators meet all of the electrical demand for the building.
- **4-Track schedule** tries to have the generators meet all of the electrical demand determined in a user-defined schedule.
- **5-Follow thermal** is used for co-generation systems where the generators are to be run mainly to meet the thermal demand and any excess electricity can be exported to the grid.
- **6-Follow thermal limit electrical** is as above for **5-Follow thermal** but in this case generator output is restricted to a maximum of the building’s current electrical demand so that no electricity is exported.

The **2-Demand limit**, **3-Track electrical** and **4-Track schedule** schemes will sequentially load the available generators. All demand not met by available generator capacity will be met by purchased electrical. Therefore, if **2-Demand limit**, **3-Track electrical**, or **4-Track schedule** is used and the available generators are not able

to meet demand, then purchased electricity will be used to offset the difference. If a generator is needed in the simulation for a small load and it is less than the minimum part load ratio the generator will operate at the minimum part load ratio and the excess will either reduce demand or the excess energy will be available for returning to the electric grid.

The **5-Follow thermal** and **6-Follow thermal limit electrical** schemes are for heat due to co-generation and run the generators to meet the thermal demand. The **5-Follow thermal** scheme allows excess electrical generation to be exported to the grid, while the **6-Follow thermal limit electrical** scheme restricts generator output to a maximum of the building's current electrical demand so that no electricity is exported. The thermal demand is determined from the plant modelling and depends on the flow requested by other components on the demand side of the plant loop, the loop temperatures, and the loop temperature set point. The electric load centre converts the thermal load to an electrical load using a nominal ratio of the thermal to electrical power production for each generator. For these schemes, the generator needs to be connected to the supply side of a plant loop and components that request hot water need to be on the demand side of the plant loop. This is different than the usual configuration for electrical following schemes where the generator is put on the demand side and request flow for the purposes of cooling the generator. Therefore a switch from one of the electrical-based operating schemes to one of the thermal-based operating schemes requires a substantial change in plant topology.

If the load centre includes electrical storage, then the choice of operating schemes will also affect how storage is managed.

Note: The **5-Follow thermal** and **6-Follow thermal limit electrical** schemes will only work for generators that are placed on the supply side of a plant loop and are being run to satisfy thermal load. When generators are run to satisfy electrical load (**1-Base load**, **2-Demand limit**, **3-Track electrical** and **4-Track schedule** scheme types), they're located on the demand side and request flow rate for cooling purposes only.

Technical

For all operating schemes except **1-Base load**, a total electric load reduction target (or thermal load converted to electrical equivalent) is established for the load centre based on the specific operating scheme. The load centre then requests that its generators operate, one-by-one in the order specified, until the target is met or exceeded. Generators that are not scheduled as 'available' for the simulation time step are not called to operate. The requested power demand to be met by each generator is the smaller of the nominal 'rated' electric power output (as specified in the Generators object) or the remaining total electric load reduction target for the load centre. After each electric generator is requested to operate, the actual electric power delivered by the generator, which may be greater than or less than the requested amount due to inputs specified in the generator performance model, is used to update the remaining total electric power target for the other generators associated with this load centre.

Most of the operating schemes will sequentially load the available electric load centres and generators. EnergyPlus can accept multiple Electric load centres with different operating schemes. Because of this, there are two levels of reporting, one for the whole building and a second for each load centre. The whole-building results are managed with the internal meters for the entire model. The individual load-centre results are summed for those generators connected to a particular load centre. The total electricity purchased is reported both in power and energy units. This value is positive when the amount of energy is purchased from the utility. This value can be negative when the total electricity produced is greater than the facility electrical needs. The excess will either be available for storage or to sell back to the electric utility company.

Demand Limit Scheme Purchased Electric Demand Limit

The demand limit above which the generators will try and meet the entire electrical load on the building minus the photovoltaic array if available (in W).

Track schedule

When the **4-Track schedule** option is used then you should select a schedule containing values for the "demand" loads placed on the generator(s). The schedule values should be in Watts.

Electrical buss type

This alpha field is used to describe how the electric load centre is configured with respect to any power conditioning and/or storage equipment. There are five configurations for load centres available by using one of these keywords:

- [1-Alternating current](#)
- [2-Alternating current with storage](#)
- [3-Direct current with inverter](#)
- [4-Direct current with inverter DC storage](#)
- [5-Direct current with inverter AC storage](#)

All the generators connected to a specific load centre need to be of the same type (all AC or all DC). If the generators are DC, then an inverter is needed to convert the DC to AC.

Alternating Current

The most basic configuration is selected with the keyword “Alternating Current” for the Electrical Buss Type, shown in the following diagram.

AC power out

The Alternating current load centres have AC generators with no storage and behave in the following way. All electric demand not met by the sum of the electrical power produced by the available generators will be met by purchased electricity. If a generator is needed in the simulation for a small load and the load is less than the generator's minimum part load ratio, the generator will operate at the minimum part load ratio and the excess will either reduce demand or the excess energy will be exported back to the electric utility company. The purchased electrical demand limit is the user input for the demand limit above which the generators will try and meet the entire electrical load on the building. It is possible to set up load centres with inconsistent or conflicting operating schemes, so users need to be careful.

Alternating current with storage

A configuration with AC generators with on-site electrical storage is selected using the **2-Alternating current with storage** Electrical buss type and is shown in the following diagram.

The **Alternating current with storage** load centres attempt to augment the generator electricity production so that the power requests are met. Storage control logic is discussed below under Electrical Storage.

Direct current with inverter

The basic configuration for photovoltaic generators is selected using the **3-Direct current with inverter** electrical buss type and is shown in the following diagram.

The **Direct current with inverter** load centres collect DC power from various PV arrays, run the DC power through an inverter and produce AC power. The PV arrays produce DC power based on the availability of sunshine and do not respond to load requests made by the electric load centre. The AC output from the inverter is what is recorded as electricity production.

Direct current with inverter DC storage

If the PV-based load centre is equipped with DC electrical storage that is connected before the inverter, then the buss type should be **4-Direct current with inverter DC Storage** and is shown in the following diagram.

The **Direct current with inverter DC storage** load centres charge or draw DC power to meet the requested electrical load.

Direct current with inverter AC storage

If the PV-based load centre is equipped with AC electrical storage that is connected after the inverter, then the buss type should be **5-Direct current with inverter AC storage** and is shown in the following diagram.

Inverter

The [inverter](#) selection option is only used if the [Electrical buss type](#) is set to **3-Direct current with inverter** and it allows you to select the inverter connected to this load centre (if any). There are three types of inverter models available:

- Simple,
- Look up table, or
- Function of Power.

Storage

The [storage](#) selection option is used to identify the electrical storage connected to this load centre (if any). It is only used if the Electrical Buss Type is set to **4-Direct current with inverter DC storage** or **5-Direct current with inverter AC storage**.

Cost

Distribution and electrical cost

Enter the cost of the electrical power distribution and any other related costs here.

The cost of the panels themselves is entered on the Constructions tab under the [Solar Collectors](#) header.

The cost entered here on the load centre will be included with the other renewable equipment costs under:

- Basic:
- UNIFORMAT II: F10 Special construction
- NRM1:

Note: In order for the cost of renewable systems such as solar PV and hot water panels and wind turbines to be included in the Construction cost report (and any cost-related KPIs used in an optimisation) those generators must be specified in an "Electric Load Centre" on page 528.

Generator List

On the Generator List tab you can define up to 30 generators per Electric load centre. Set the number of generators and select the generator to be used for each.

For DC Electric load centres the generators will be [PV solar collectors](#), [Construction BIPV](#) or [Glazing BIPV](#) systems.

For AC centres the generators will be [Wind turbines](#), or [Generators](#).

Tip: To model multiple PV panels without the need to draw all of the building panels you can reference the same panel multiple times on the Generator list tab. You should only do this if all of the panels have the same shading and if the shading cast by the panels does not impact on the building.

How To Model Wind Turbine Systems

How To Model A Wind Turbine System - Summary

You can include one or more [wind turbines](#) in your model by following the instructions below.

1. First define the electric side of the wind turbine system at building level on the **Generation** model data tab under the [On Site Electricity Generation](#) header:
 - a. Check the **Include electric load centres** check box.
 - b. Add an [Electric load centre](#) and edit the details of the system.
 - c. Use one of [the AC buss types](#).
 - d. If using storage define the [Storage](#) type.
 - e. Select the [wind turbine](#) on the [Generator list](#) tab.
 - f. Make sure that having defined a new [Electric load centre](#) that the correct one is selected on the **Generation** model data tab.
2. When the simulation is finished you can view wind turbine contributions in absolute and % terms on the Summary tab:

Electric Loads Satisfied

Total On-Site and Utility Electric Sources	418141.37	100.00
Total Electricity End Uses	418141.37	100.00

Wind Turbines

Wind turbines convert the kinetic energy of the surrounding air-stream into electricity. The EnergyPlus wind turbine model calculates the electrical power produced based on the characteristics of the turbine itself as well local environmental conditions such as wind speed and density of air at the height of the systems. The model obtains the weather information from the simulation weather data file and then determines the wind speed and air density at the specific height of the system. It also requires the user to input the annual average wind speed measured at the local site and the height of the measurement so that it factors in differences between the weather file wind data and the local wind data.

Tip: Wind turbines are included in the model by specifying them on the [Generator list](#) tab of the Electric load centre dialog when one of the a.c. [Buss types](#) is selected.

Technical

The model employs the general kinetic energy equation to calculate the performance characteristics of the horizontal axis wind turbine (HAWT) systems. It provides a simple approximation algorithm when the power coefficient, C_p , is available which represents the efficiency of the wind turbine in the wind power extraction from the ambient air stream. It also allows the user to input experimental constants so that the power coefficient can precisely be determined according to the characteristic of the airfoil of the system. As for the vertical axis wind turbine (VAWT) systems, it employs the general mathematical equations for straight-bladed Darrieus-type VAWT systems, which are common to VAWT systems. Various types of VAWT systems such as the Savonius-type and the curved-blade (or egg-beater) type may be simulated with this same model. It includes two different types of dynamic power control: Fixed Speed Fixed Pitch (FSFP) and Variable Speed Fixed Pitch (VSFP). Currently, it does not include an algorithm for modelling pitch control such as Fixed Speed Variable Pitch (FSVP) and Variable Speed Variable Pitch (VSVP). The model also has

the ability to account for transient losses associated with the power produced during dynamic control by a user-specified fraction.

The model does not include detailed algorithms for generators and inverters due to concerns for computational convergence, time, and usability. Instead, all conversion losses of these subsystems are included by applying a user-supplied total system efficiency to the maximum power extraction of the wind turbine. The field of the total system efficiency must be specified by the user.

Name

A unique user assigned name for a particular wind turbine system. Any reference to this unit by another object will use this name.

Availability schedule

The schedule selected here defines the times when the wind turbine system can run. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off and will not operate for the time period.

Rotor type

This field is the type of axis of the wind turbine. Select from 2 types

- **1-Horizontal axis** or
- **2-Vertical axis**.

A different algorithm is used in the calculation of the electrical power output of the wind turbine depending on the Rotor type.

Power control

This field is the type of rotor control for the wind turbine. This protects the system against the overloading for a system with no speed or pitch control and also to maximize the energy yield for the system. Four different control types are classified in the literature:

- **1-Fixed Speed Fixed Pitch** (FSFP),
- **2-Fixed Speed Variable Pitch** (FSVP),
- **3-Variable Speed Fixed Pitch** (VSFP), and
- **4-Variable Speed Variable Pitch** (VSVP).

Currently, FSFP and VSFP types can be modelled in EnergyPlus. The other two types will be modelled as VSFP. If the first FSFP control type is chosen, the model assumes the maximum power at a fixed rotor speed when the power output predicted is greater than the maximum until the rotor speed reaches the maximum wind speed (see next field). If one of the last three control options is chosen, the model assumes that the system produces a constant power at the rated wind speed when the wind speed is between the rated wind speed and cut-out wind speed. The default value is **3-Variable Speed Fixed Pitch** (VSFP).

Rated rotor speed

This field is the maximum rotational speed of the rotor at the rated power of the wind turbine in rev/min (revolution per minute). It is used to determine the tip speed ratio of the rotor and relative flow velocity incident on a single blade of the VAWT systems.

Rotor diameter

This field is the diameter of the rotor (in m or ft). Note that this field is not the height of the blade, but the diameter of the perpendicular circle from the vertical pole in the VAWT systems. It determines the swept area of the rotor of the HAWT systems and the chordal velocity of the VAWT systems.

Overall height

This field is the height of the hub of the HAWT system, or of the pole of the VAWT system (in m or ft). It is necessary to estimate local air density and the wind speed at this particular height where the wind turbine system is installed.

Number of blades

This field is the number of blades of the wind turbine. The azimuth angle of the rotor of the VAWT system is determined by dividing 360 degree by this field so that the model determines the chordal velocity component and the normal velocity component of the system. The default value is 3.

Rated power

This field is the nominal power output of the wind turbine system at the rated wind speed (in W or Btu/hr). Note that the maximum power of the system should be entered with no control, i.e. FSFP control type, can physically produce. Manufacturer data sometimes describes this as “peak power” or “rated capacity”. If the local wind speed is greater than the rated wind speed, the model assumes constant power output of this field.

Rated wind speed

This field is the wind speed that the wind turbine system indicates the peak in the power curve (in m/s or ft/min). The system produces the maximum power at this speed and the speed of the rotor is managed based on this wind speed.

Cut in wind speed

This field is the lowest wind speed where the wind turbine system can be operated (in m/s or ft/min). No power generation is achieved as long as the ambient wind speed is lower than this speed.

Cut out wind speed

This field is the greatest wind speed (in m/s or ft/min). When the wind speed exceeds this value, the wind turbine system needs to be stopped because of inefficiencies in the system. All systems that have either pitch or speed control must be stopped when the ambient wind speed exceeds this speed. Note that the user should input a wind speed above which physical damage to the system might be caused in the case of a FSFP system. It appears as “extreme/survival/design wind speed” in the literature. The system will be turned off when the ambient wind speed is over this speed.

Fraction system efficiency

This field is the overall system efficiency of the wind turbine system. It includes all the conversion losses as well as transient losses during the dynamic control when the ambient wind speed is between the rated wind speed and cut-out wind speed (see previous fields).

The user also has the ability to specify delivery losses from the system to the local area. If the user does not enter a fraction, the model assumes the default value of 0.835. Note that the fraction must be between zero and one.

Maximum tip speed ratio

This field is the maximum tip speed ratio between the rotor velocity and ambient wind velocity. The rotor speed varies with this ratio to maximize the power output when the rotor control types are variable speed ones. This field allows the user to adjust the power output from the particular system or to find the optimal tip speed ratio of the system. Optimal tip speed ratio is dependent on the number of blades. It is typically about 6, 5, and 3 for two-bladed, three-bladed, and four-bladed rotor, respectively. For the vertical axis wind turbine, it is smaller than horizontal axis wind turbine, and varies with the chord area. The default and maximum values are 5.0 and 12.0.

Power calculation method

There are 2 models to choose from:

- **1-Simple** - simple approximation model employs the general kinetic energy equation and a [Maximum power coefficient](#) to calculate power extraction from the wind.
- **2-Analytical** - The power output of the turbine is calculated from the [Power coefficient equation](#) using 6 parameters C_{1-6} .

Maximum power coefficient

This is the maximum fraction of power extraction possible from the ambient wind and is required only when the **1-Simple** Simulation method is selected. This value can be calculated from the power curve published in most manufacturers' specifications by using the kinetic energy equation as:

$$C_p = \frac{P}{0.5\rho AV^3}$$

where:

P = power production at the rated wind speed [W]

ρ = density of air [kg/m³]

A = swept area of rotor [m²]

V = rated wind speed [m/s]

C_p = power coefficient

The maximum and default coefficient values are 0.59 and 0.35 respectively.

Annual local average wind speed

This is the local annual average wind speed that represents a representative wind profile at the location of the system (in m/s or ft/min). It is used to factor the difference in wind speed between the weather file wind data and the locally measured wind data so that the model minimizes uncertainties caused by improper wind data at the particular location. Considerable differences between the weather file wind data and the local wind data typically appear so it is important to consider this carefully in order to use accurate local wind data in the simulation. The model internally determines a multiplier and it is multiplied by the weather file wind data adjusted at the height of the system.

Height for local average wind speed

This is the height that the local wind speed is measured (in m or ft). The annual average wind speed (see previous field) input by the user is internally recalculated by existing EnergyPlus functions at the height of the local station. This modified wind speed is then factored and applied to the weather file wind data. The minimum and default values are zero and 50m.

Vertical Axis

For vertical axis turbines you can enter details on the Blade chord area, drag coefficient and lift coefficient on the Vertical Axis tab.

Blade chord area

This is the blade chord area of a single blade of VAWT system in (m² or ft²). It is necessary to determine the net tangential and normal forces of a single blade.

Blade drag coefficient

This is the blade drag coefficient for a specific blade. It is for determining the tangential and normal force coefficients with the blade lift coefficient (below) so that the model can calculate the power output from the system. The user should be able to obtain this parameter for a specific blade from the manufacturers' data. This field is only required for VAWT systems.

Blade lift coefficient

This field is the blade lift coefficient for a specific blade. It is for determining the tangential and normal force coefficients with the blade drag coefficient (above) so that the model can calculate the power output from the system. The user should also be able to obtain it for a specific blade from the manufacturers' data. This field is only required for VAWT systems.

Power Coefficients

For horizontal axis turbines using the [2-Analytical Power calculation method](#) the Power coefficients can be entered on the Power Coefficients tab.

Power coefficient parameters C1-C6

These six fields are the parameters for the power coefficient equation shown below. These fields are used to determine the power coefficient of the system. The analytical approximation model of the power coefficient in EnergyPlus is:

$$C_p = C_1 \left(\frac{C_2}{\lambda_i} - C_3 \theta - C_4 \theta^x - C_5 \right) e^{-\frac{C_6(\lambda, \theta)}{\lambda_i}}$$

with

$$\frac{1}{\lambda_i} = \frac{1}{\lambda + 0.08\theta} - \frac{0.035}{\theta^3 + 1}$$

where:

C_p = power coefficient

C_{1-6} = empirical power coefficient parameters

λ = tip speed ratio (often known as TSR)

λ_i = tip speed ratio at ith time step

θ = azimuth angle of the pitch, 0 [degree]

The default values are given in the table below.

C_1	C_2	C_3	C_4	C_5	C_6
0.5176	116	0.4	0.0	5.0	21

Electrical Storage

Electrical energy provided by generators such as PV panels and wind turbines can be stored on site for later use using Storage components.

Tip: Electric storage devices are included in the model by specifying them on the [Electrical load centre](#) dialog when one of the storage [Electrical buss types](#) has been selected.

There are 2 ways to model the define the performance of the electrical storage device:

- [1-Simple storage](#) - simple definition of the performance of the storage device that is not intended to represent any specific type of storage technology.
- [2-Battery](#) - more detailed performance definition of a battery using the kinetic battery model.

The type of storage device is defined by selecting the appropriate **Category** option on the Storage dialog.

Simple Storage

The Simple storage option is accessed by selecting the **Simple storage** category on the [Storage](#) dialog. The Simple type of Electrical storage component is used to model storage of electricity in an [Electric load centre](#). It is a simple model that does not attempt to represent any of the detailed performance characteristics of a real storage device such as a battery. The type of power, AC or DC, depends on the configuration chosen as the [Electrical buss type](#) in the [Electric load centre](#).

Name

This field contains a unique name for the electric storage device.

Category

There are 2 categories to choose from:

- **Simple storage** for a simple definition of the performance of batteries or other storage device.
- **Battery** for a more detailed performance definition of a battery

The Category selected affects the type of model used and the data to be entered on the Storage dialog.

Availability schedule

This schedule describes the times when the storage device is available. If storage is not available, by scheduling a value of 0, then no electrical energy can be stored or drawn from the device. Any non-zero schedule value means the devices is available. If this field is blank, the schedule has values of 1 for all time periods.

Heat Gain To Zone

Attach to a zone

If the losses from the storage device should be represented as heat gains to a zone then check this box and select the zone in the next field.

Zone

This field contains the name of the thermal zone where the storage device is located. The selected zone will receive the storage losses as heat gains.

Radiative fraction for zone heat gains

This field contains the fraction of storage losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses are convective. This field is only used when a zone is attached.

Simple Options

Nominal energetic efficiency for charging

This field contains the charging efficiency. This is the energetic efficiency of storing electrical energy in the storage device. A value of 1.0 means the device does not lose any energy when charging.

Nominal discharging energetic efficiency

This field contains the discharging efficiency. This is the energetic efficiency of drawing electrical energy from the storage device. A value of 1.0 means the device does not lose any energy when drawing power.

Maximum storage capacity

This field describes the maximum amount of energy that can be stored in the device in Joules. Once the storage device is full, no additional energy can be stored in it.

Maximum power for discharging

This field describes the maximum rate at which electrical power can be discharged from the storage device (in W).

Maximum power for charging

This field describes the maximum rate at which electrical power can be stored in the device (in W).

Initial state of charge

This field describes the value for the initial state of charge in Joules. This is used to model the storage device as having some amount of stored energy at the beginning of the simulation period.

Battery

The Battery option is accessed by selecting the Battery category on the [Storage](#) dialog. Batteries can be used to store charge in an [Electric load centre](#). The battery bank is a collection of one or more individual battery modules. Given the surplus or deficit power from the electrical system and the state of charge from the previous time step, this object can model the voltage, current, and energy losses with charging and discharging during each time step. The cumulative battery damage can be also modelled and reported at the end of each simulation run.

The battery component allows both Lead-Acid and Nickel Cadmium batteries to be simulated. With input parameters derived from specific battery tests, the object is expected to support other battery types such as Lithium-ion batteries.

The kinetic battery model assumes that part of the battery's energy storage capacity is immediately available in discharging or charging while the rest is chemically bound. As a function of constant current, the battery capacity is related to three parameters: the maximum capacity at infinitesimal current, the capacity ratio of available charges, and the conversion ratio between available charges and bound charges. These parameters are usually obtained via curve fitting based on battery data sheets or test data.

Each individual battery module is modelled as a voltage source in series with an electrical resistance. KiBaM assumes that the internal resistance is constant and the open circuit voltage varies with the electric current, the state of charge and the operation mode (charging or discharging). For an individual battery module, the open circuit voltage at any time is correlated to the voltage at fully charged/discharged state and three other regression coefficients. These regression coefficients are usually obtained via curve fitting based on battery test data.

The object offers user the option to perform battery life calculation. If battery life is modelled, the user needs to provide a group of coefficients for the correlation between the number of cycles for battery failure and the corresponding cycle range. More detailed information can be found in the [Engineering Reference](#).

Name

This alpha field contains the identifying name for the battery bank.

Category

There are 2 categories of electrical storage device to choose from:

- [Simple storage](#) for a simple definition of the performance of batteries or other storage device.
- **Battery** for a more detailed performance definition of a battery

The Category selected affects the type of model used and the data to be entered on the Storage dialog.

Availability schedule

This alpha field contains the schedule name (ref. Schedule) that describes when the battery is available. A schedule value greater than 0 (usually 1 is used) indicates that electrical energy can be stored or drawn from the battery. A value less than or equal to 0 (usually 0 is used) denotes that the battery is not available. If this field is blank, the schedule has values of 1 for all time periods.

Heat Gain To Zone

Attach to a zone

If the losses from the storage device should be represented as heat gains to a zone then check this box and select the zone in the next field.

Zone

This field contains the name of the thermal zone where the battery is located. Entering a valid name of zone here will direct EnergyPlus to include the energy storage losses as heat gains to the named thermal zone. If the battery is not within a thermal zone, this field can be left blank and the thermal energy associated with storage losses is removed from the building model.

Radiative fraction for zone heat gains

This field contains the fraction of storage losses that enter the zone as long-wave thermal radiation. This numeric field should have a value between 0.0 and 1.0. The balance of the losses is convective. This data is only required when the [Attach to a zone](#) option is checked.

Battery Storage

Number of battery modules in parallel

This field defines the number of modules connected in parallel in the battery bank.

Number of battery modules in series

This field defines the number of modules connected in series in the battery bank. The total number of modules in a battery bank is equal to the number of modules in parallel times the number of modules in series.

Maximum module capacity

This field indicates the maximum capacity of one battery module. It is evaluated as the total Amp-hours available when a full battery is discharged at infinitesimal current. This capacity is for an individual battery module, not for the whole battery bank. The maximum capacity can be found from manufacture's data or derived from test data by curve fitting.

Initial fractional state of charge

This field describes the initial state of charge in terms of the fraction of maximum capacity as defined in the previous field.

Fraction of available charge capacity

The kinetic battery model assumes that battery is a two-tank electrical energy storage device: an available tank and a bound tank. The available tank can be immediately charged or discharged, while the bound tank can only be charged or discharged via the available tank.

This field specifies the fraction of total charge in the battery that is part of the available tank. The ratio of available charge capacity to total capacity is a parameter usually derived from test data by curve fitting.

Change rate from bound charge to available charge

This field specifies the rate at which the charge flows between the available tank and the bound tank. It is a parameter used to calculate the conversion between available charge and chemically bound charge when charging and discharging the battery. This parameter is usually derived from test data by curve fitting.

Fully charged module open circuit voltage

This field indicates the open circuit voltage for a fully charged battery module. It can be found from manufacture's data or battery tests.

Fully discharged module open circuit voltage

This field indicates the open circuit voltage for a fully discharged battery module. It can be found from manufacture's data or battery tests.

Voltage change curve for charging

This field specifies the name of a [Rectangular Hyperbola 2 performance curve](#) that determines the change of open circuit voltage (ΔE) as a function of the battery state of charge in charging. The change of open circuit voltage is relative to a fully discharged battery. The curve has the following form:

$$\Delta E = (C_1 * X) / (C_2 + X) + C_3 * X$$

where X is the battery charge divided by the maximum capacity at a given current. More details can be found from the [Engineering Reference](#).

Voltage change curve for discharging

This field specifies the name of a [Rectangular Hyperbola 2 performance curve](#) that determines the change of open circuit voltage (ΔE) as a function of the battery state of charge in discharging. The change of open circuit voltage is relative to a fully charged battery. The curve has the following form:

$$\Delta E = (C_1 * X) / (C_2 + X) + C_3 * X$$

where X is the removed charge divided by the maximum capacity at a given current. More details can be found from the [Engineering Reference](#).

Module internal electrical resistance

This field specifies the battery internal resistance in ohms. In theory, the electrical resistance within the battery varies with the state of charge and depends on whether it is in charging or discharging. In the kinetic battery model, the internal resistance is assumed as constant and the terminal voltage varies with current and state of charge. The internal resistance may be obtained from the battery manufacture or battery test data. Note that the field is for an individual module, not for the whole battery bank.

Maximum module discharging current

This field indicates the maximum current at which the battery can be discharged continuously. The limit on discharge current is usually defined by the battery manufacture to avoid battery damage. The limit is for an individual battery module.

Module cut-off voltage

This field specifies the minimum allowable voltage, below which the battery is generally regarded as empty. The cut-off voltage is usually defined by the battery manufacture and it is for an individual battery module.

Module charge rate limit

This field specifies the limit on charging current relative to the remaining charge until the battery is full. This limit reflects the common practice that the charge rate is reduced as the battery gets more charged.

Battery Life

Battery life calculation

This checkbox indicates whether the battery life model is activated in the simulation. If the battery life model is activated, the following 2 inputs are required.

Number of cycle bins

This field specifies the number of equally ranged cycle bins in battery life simulation. If 10 bins are used, the cycle ranges will include 10%, 20%, ..., 100%.

Battery cycle life curve

This field specifies the [Double Exponential Decay Curve](#) that correlates the cycles of battery failure (C_F) and fractional depth of discharge (R). The curve is:

$$C_F = C_1 + C_2 e^{C_3 R} + C_4 e^{C_5 R}$$

Inverters

Inverters are used to model conversion from Direct Current (DC) to Alternating Current (AC) in an electric load centre that contains photovoltaic modules. Such a load centre has an array of photovoltaic modules that feed an inverter with DC power and the inverter produces AC power.

Tip: Electric inverters can be included in the model by selecting them on the [Generator List](#) tab of the Electrical load centre dialog when one of the d.c. [Electrical buss types](#) has been selected.

Three types of inverter can be defined:

- [Simple](#) - fixed conversion efficiency.
- [Function of Power](#) - conversion efficiency depends on power and is defined using a performance curve.
- [Lookup table](#) - conversion efficiency depends on power and is defined using a look up table.

The type of inverter can be selected using the **Category** option on the Inverter dialog.

Note: Each inverter defined in the model can only be used within a single Load centre. In other words, each DC load centre must have its own a unique inverter selected.

Inverter - Simple

Simple [inverters](#) use a single fixed conversion efficiency value.

General

Name

The name of the inverter entered here must also be unique across all other inverters in the model.

Category

Select the type of inverter from the options below:

- **Simple** - fixed conversion efficiency.
- **Function of Power** - conversion efficiency depends on power and is defined using a performance curve.
- **Lookup table** - conversion efficiency depends on power and is defined using a look up table.

Availability schedule

The schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power and consume ancillary power during standby. If the Inverter is scheduled to be unavailable but it is being supplied with DC power anyway, then the energy is dissipated as heat.

Simple

Inverter efficiency

This field contains the value for inverter efficiency. In the simple model, efficiency is a constant. This is the so-called 1-term model. Input data for different types of inverters is available at:

https://www.gosolarcalifornia.org/equipment/inverter_tests/summaries/

The “CEC Efficiency” would be the value to enter here.

Heat Gains To Zone

Attach to a zone

If the inverter’s losses are to be modelled as heat gains to a zone in the building thermal model then check this option. Otherwise inverter losses are considered to be lost to outside.

Zone

When including inverter losses and heat gains to a zone select the building zone where the inverter is located.

Radiative fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This data is only required when including inverter losses and gains to a zone.

Inverter - Function Of Power

Function of Power [inverters](#) use a function of normalized power to calculate the efficiency of conversion from DC to AC.

General

Name

The name of the inverter entered here must also be unique across all other inverters in the model.

Category

Select the type of inverter from the options below:

- [Simple](#) - fixed conversion efficiency.
- [Function of Power](#) - conversion efficiency depends on power and is defined using a performance curve.
- [Lookup table](#) - conversion efficiency depends on power and is defined using a look up table.

Availability schedule

The schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power and consume ancillary power during standby. If the Inverter is scheduled to be unavailable but it is being supplied with DC power anyway, then the energy is dissipated as heat.

Function Of Power

Efficiency function of power curve

This is the curve representing the relationship between DC power input into the inverter and the efficiency with which that power is converted to AC. The curve can be of type [Linear](#), [Quadratic](#), or [Cubic](#). The curve's "x" value is DC power input normalized by the [Maximum continuous input power](#) (below). The result of the curve should be power conversion efficiency expressed as a fraction between 0.0 and 1.0.

Rated maximum continuous input power

This field contains the rated power input (in W). This is value used to normalize input power for use with the curve named in the previous field. This is DC power from the PV arrays going into the inverter.

Minimum efficiency

This field contains a minimum bound on the inverter efficiency. This value will be used as a limit on the curve's result.

Maximum efficiency

This field contains a maximum bound on the inverter efficiency. This value will be used as a limit on the curve's result.

Minimum power output

This field contains a lower limit on the AC power produced by the inverter (in W). If the resulting power output would be below this level, then the inverter is assumed to not produce any power and is in stand by mode. All DC power input is lost (unless it is going into storage).

Maximum power

This field contains an upper limit on the AC power produced by the inverter (in W). If the resulting power output would be above this level, then the power produced is capped at this level with the rest of input power converted to losses (unless it is going into storage).

Ancillary power consumed In standby

This field contains the ancillary power (in W) used by the inverter when not producing AC power. This is AC electricity consumed in standby mode. Standby mode occurs when the inverter is scheduled to be available but the incoming DC power is too low.

Heat Gains To Zone

Attach to a zone

If the inverter's losses are to be modelled as heat gains to a zone in the building thermal model then check this option. Otherwise inverter losses are considered to be lost to outside.

Zone

When including inverter losses and heat gains to a zone select the building zone where the inverter is located.

Radiative fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This data is only required when including inverter losses and gains to a zone.

Inverters - Lookup Table

Lookup Table inverters model DC to AC power conversion efficiency by interpolating values from a look up table. The data structure has been designed to be used with data contained in the Inverter Performance Test Summaries available at:

https://www.gosolarcalifornia.org/equipment/inverter_tests/summaries/

All of the data needed for this object can be found there by make and model of inverter. The core of the data set is a 3x6 matrix of efficiency at different voltage and power levels. These form the look up table used in the model. Note that EnergyPlus PV models currently model only power and not the voltage and current situation. Therefore, only the nominal voltage data are used. This is the middle row of data in the Go Solar summaries.

General

Name

The name of the inverter entered here must also be unique across all other inverters in the model.

Category

Select the type of inverter from the options below:

- [Simple](#) - fixed conversion efficiency.
- [Function of Power](#) - conversion efficiency depends on power and is defined using a performance curve.
- [Lookup table](#) - conversion efficiency depends on power and is defined using a look up table.

Availability schedule

The schedule that describes when the inverter is available. If the inverter is scheduled to not be available, by scheduling a value of 0, then it cannot produce AC power and will not consume ancillary power during standby. Any non-zero schedule value means the inverter is available to produce AC power and consume ancillary power during standby. If the Inverter is scheduled to be unavailable but it is being supplied with DC power anyway, then the energy is dissipated as heat.

Lookup Table

Rated maximum continuous output power

This field contains the rated maximum continuous output power (in W).

Night tare loss power

This field contains the “night tare loss” (in W). This is modelled as ancillary power consumed during standby.

Nominal voltage input

This field contains the nominal DC input voltage (in V). This is “Vnom” in the [Go Solar test summaries](#).

Efficiency At Nominal Voltage

At 10% Power

The fractional efficiency at nominal voltage and 10% power.

At 20% Power

The fractional efficiency at nominal voltage and 20% power.

At 30% Power

The fractional efficiency at nominal voltage and 30% power.

At 50% Power

The fractional efficiency at nominal voltage and 50% power.

At 75% Power

The fractional efficiency at nominal voltage and 75% power.

At 100% Power

The fractional efficiency at nominal voltage and 100% power.

Heat Gains To Zone

Attach to a zone

If the inverter’s losses are to be modelled as heat gains to a zone in the building thermal model then check this option. Otherwise inverter losses are considered to be lost to outside.

Zone

When including inverter losses and heat gains to a zone select the building zone where the inverter is located.

Radiative fraction

This field contains the fraction of inverter thermal losses that enter the zone as long-wave thermal radiation. This should be a factor between 0.0 and 1.0. The balance of the losses is convective. This data is only required when including inverter losses and gains to a zone.

Economics

Economics tab in model data

When using [Detailed HVAC](#) you can define 3 aspects of building economics on the **Economics** tab at building level:

- [Tariff analysis](#) - to calculate the costs of the building utility usage.

- [Construction costs](#) - include construction costs calculated on the [Cost and Carbon](#) tab in simulation inputs.
- [Life-cycle cost](#) - (LCC) to calculate the whole building life-cycle cost.

The data entered on the Economics tab will be passed to EnergyPlus to be included in simulations.

Note: You must have Economics and HVAC licence modules to work with the data on this tab. Detailed HVAC is required to provide access to components with the full set of EnergyPlus fuel types for tariff analysis and LCC. Simple HVAC cannot access tariff analysis (and hence LCC) as it uses ideal loads HVAC systems rather than EnergyPlus fuels.

Tariff Analysis

To calculate the costs of the utilities, fuels etc use the tariff analysis section of the Economics tab.

Include tariff analysis

To include a tariff analysis check the Include tariff analysis checkbox.

Number of tariffs

Enter the number of tariffs to be included in the simulation. You will be able to select a Tariff analysis component for each.

Tariff 1, 2 etc

Select the [Tariff analysis](#) component describing the characteristics of each tariff to be included. Up to 5 different tariffs can be selected depending on the **Number of tariffs** selected above.

Construction Costs

Include construction cost in simulation inputs

To include the construction capital cost of the building in the simulation you should check this checkbox. This must be done to include construction cost in a Life cycle cost calculation.

Summary results from the most recently run [Cost calculation](#) on the Cost and Carbon tab will be included in the "Component cost" component which is selected by default.

Construction cost

Select the [Construction cost](#) component.

Life Cycle Cost

Include life cycle cost analysis

To include a life cycle cost analysis check this check box.

Life cycle cost

Select the [Life cycle cost](#) component defining the analysis to be included in the simulation.

Tariff Analysis

Background

Monthly utility bills are often directly related to monthly energy consumption and monthly peak demand. DesignBuilder EnergyPlus' approach to tariff analysis is to allow you to model the individual component charges that make up the utility bill and report the results on a monthly basis. The calculation is organised in hierarchy for economics charges illustrated below.

Any charges included in the EnergyCharges category are added together at the first step. The EnergyCharges, DemandCharges and ServiceCharges are added together to form the Basis. The Basis, Adjustments and Surcharges are added together to form the Subtotal. And finally the Total is obtained from the summation of Subtotal and Taxes, where the Total represents the total monthly charges on that tariff for the energy source used. In addition, each category name is usually used as a source variable when setting charges and doing tariff calculation.

Multiple Tariffs can be modelled, and it is common that electric and gas utilities have more than one rate that may be used. However, only one Tariff for each Output Meter object and Group Name is shown in the Economics Summary Report. The one that is shown in the report is chosen by first eliminating Tariffs that are not qualified due to their Qualify objects. If more than one Tariff object remains, the one that has the lowest cost for a combination of an Output Meter and Group Name will be selected. If the Group Name field is not checked, then the lowest cost Tariff object is chosen for each Meter.

Working With Tariff Analysis

DesignBuilder provides access to EnergyPlus' tariff analysis capabilities by allowing you to define one or more tariffs using the Tariffs dialog. To include a tariff analysis in your simulation, start by checking the **Include tariff analysis** checkbox. This allows you to set the number of tariffs to be defined and to assign a Tariff component to each one.

To edit a tariff, for example Tariff 1, click on the associated browse control and use the **Edit/view selected item** Info panel toolbar icon. This opens the Tariffs dialog.

There are 5 tabs on the Tariffs dialog:

- [Tariff](#)
- [Charge](#)
- [Qualify](#)
- [Ratchet](#)
- [User Variables](#)

See also:

- "Tariff Examples" on page 567

Tariff Analysis - Tariff Tab

Tariff tab on [Tariff Analysis](#) dialog

Tariff

Tariff name

The field gives the name of the tariff to be modelled. Tariffs are sometimes called rates. The name is used in identifying the output results and in associating all of the charges and other objects that make up a tariff.

Description

Enter a description for the tariff.

Category

Select a category for the tariff from:

- Electricity tariffs
- Gas tariffs
- Other tariffs

Output meter name

The name of any relevant meter defined by EnergyPlus but normally set to one of:

- 1-Electricity:Facility,
- 2-Gas:Facility,
- 3-ElectricityPurchased:Facility,
- 4-ElectricitySurplusSold:Facility,
- 5-ElectricityNet:Facility,
- 6-Other Defined Meter

This output meter name must point to a valid meter, otherwise it will lead to unexpected results.

Usually:

- the **Electricity:Facility** meter or the **ElectricityPurchased:Facility** is selected when the [buyFromUtility Buy or sell](#) option is used,
- the **ElectricitySurplusSold:Facility** meter is selected when the [sellToUtility Buy or sell](#) option is used and
- the **ElectricityNet:Facility** meter is selected when the [netMetering Buy or sell](#) option is used.

To calculate energy cost for specific energy use, the corresponding output meter name must be used (if input manually, it should be typed exactly as EnergyPlus defined). For example, if your utility cost calculation is intended for lighting electricity only, the InteriorLights:Electricity output meter name should be used here.

Note: The default **1-Electricity:Facility** option may not be suitable for models with on-site generation. In these cases Electricity:Purchased or ElectricityNet:Facility with appropriate Buy or Sell option should be chosen.

Conversion factor choice

A choice that allows several different predefined conversion factors to be used; otherwise, user defined conversion factors are used as defined in the next two fields.

The choices are:

- **1-UserDefined**
- **2-kWh**
- **3-Therm**
- **4-MMBtu**
- **5-MJ**
- **6-KBtu**
- **7-MCF**
- **8-CCF**

The following table shows the conversion factors when specifying one of the predefined choices:

Choice	Energy Conversion Factor	Demand Conversion Factor
kWh	0.0000002778	0.001
Therm	9.4781712E-09	0.00003412
MMBtu	9.4781712E-10	0.000003412
MJ	0.000001	0.0036
KBtu	9.4781712E-07	0.003412
MCF	9.4781712E-10	0.000003412
CCF	9.4781712E-09	0.00003412

Energy conversion factor

This field will be used only if Conversion factor choice is set to **1-UserDefined**. It defines a multiplier used to convert energy into the units specified by the utility in their tariff. If no conversion is required, input 1 here. This is also used for all objects (such as Charge, Qualify) used in the same tariff.

Demand conversion factor

This field will be used only if Conversion Factor Choice is set to **1-UserDefined**. It defines a multiplier used to convert demand into the units specified by the utility in their tariff. If no conversion is required, input 1 here. This is also used for all objects (such as Charge, Qualify) used in the same tariff.

Schedules

Use 'Time of use period schedule'?

Check this check box if you would like to include a time of use period schedule.

Time of use period schedule

Select the schedule that defines the time-of-use periods that occur each day. The period schedule is used to determine which variables are defined. The values for the different variables are:

- 1 is Peak
- 2 is Shoulder
- 3 is OffPeak
- 4 is MidPeak

Note: Different utilities use different terms to describe their rates. Sometimes the "shoulder" and the term "midpeak" both mean basically the same thing. To define a time of use period schedule, you do not need always use all of these terms. For terms "Shoulder" and "MidPeak", in DesignBuilder/EnergyPlus you can use either term as long as you use them consistently throughout the description of the utility tariff. Of course, you can use them both if the utility has four levels though it is very unusual.

The following variables are created automatically if these different periods are used in the schedule and include:

- peakEnergy
- peakDemand
- shoulderEnergy
- shoulderDemand
- offPeakEnergy
- offPeakDemand
- midPeakEnergy
- midPeakDemand

Some special variables are created that include only demand from one period that exceeds the demand from another period. For other months that do not exceed, the values are zero. These variables are seldom used but are available for the occasional rate that includes a clause looking at demands during one period that exceed another period.

- PeakExceedsOffPeak
- OffPeakExceedsPeak
- PeakExceedsMidPeak
- MidPeakExceedsPeak
- PeakExceedsShoulder
- ShoulderExceedsPeak

If no Period Schedule is specified then no variables mentioned above will be created.

Use 'Season schedule'?

Check this check box if you would like to include a season schedule.

Season schedule

Select the schedule that defines the seasons. The seasons are:

- 1 is Winter
- 2 is Spring
- 3 is Summer
- 4 is Autumn

The change in the season schedule must occur at the same time as the change in the Monthly Schedule. In other words, a season must end at the same time as a billing month. Variables are automatically created if a season schedule is used. These variables are set to 1 within the season and 0 for the months that are not in the season. The variables are:

- isWinter
- isNotWinter
- isSpring
- isNotSpring
- isSummer
- isNotSummer
- isAutumn
- isNotAutumn

Use 'month schedule'?

Check this check box if you would like to include a month schedule.

Month schedule

Select the schedule that defines the billing periods of the year. Normally this entry is allowed to default and a schedule will be internally used that has the breaks between billing periods occurring at the same time as the breaks between months, i.e., at midnight prior to the first day of the month. If other billing periods are used such as two month cycles or a single bill for an entire season, such as some natural gas companies do in the summer, then the month schedule may be used to redefine it. Make sure that the month schedule and season schedule are consistent, otherwise an error will be issued.

- 1 is the first month, usually January
- 2 is the second month, usually February
- 3 is the third month, usually March
- 4 is the fourth month, usually April
- 5 is the fifth month, usually May
- 6 is the sixth month, usually June
- 7 is the seventh month, usually July
- 8 is the eighth month, usually August
- 9 is the ninth month, usually September
- 10 is the tenth month, usually October
- 11 is the eleventh month, usually November
- 12 is the twelfth month, usually December

Thus, the schedule that represents this would look like the following. If no schedule is specified the following Month Schedule is used which defines the months of the year as the normal calendar months.

The use of the Month Schedule Name field is not usually required. Most utility tariffs have monthly bills and so this field would not need to be used. Specifically, if you have bills every two months, you would define a schedule to use in this field that had the value of 1 for January and February, the value of 2 for March and April, the value of 3 for May and June, etc. See below:

```
Schedule:Compact, TwoMonthBilling, number,
Through: 2/28, For: AllDays, Until: 24:00, 1,
Through: 4/30, For: AllDays, Until: 24:00, 2,
Through: 6/30, For: AllDays, Until: 24:00, 3,
Through: 8/31, For: AllDays, Until: 24:00, 4,
Through: 10/31, For: AllDays, Until: 24:00, 5,
Through: 12/31, For: AllDays, Until: 24:00, 6;
```

For other cases, some natural gas utilities define a single billing period for the summer months. In this case you would define a schedule that was 1 for January, 2 for February, 3 for March, 4 for April, 5 for May June July and August, 6 for September, 7 for October, 8 for November, 9 for December.

```
Schedule:Compact, SingleSummerBilling, number,
Through: 1/31, For: AllDays, Until: 24:00, 1,
Through: 2/28, For: AllDays, Until: 24:00, 2,
Through: 3/31, For: AllDays, Until: 24:00, 3,
Through: 4/30, For: AllDays, Until: 24:00, 4,
Through: 8/31, For: AllDays, Until: 24:00, 5,
Through: 9/30, For: AllDays, Until: 24:00, 6,
Through: 10/31, For: AllDays, Until: 24:00, 7,
Through: 11/30, For: AllDays, Until: 24:00, 8,
Through: 12/31, For: AllDays, Until: 24:00, 9;
```

Other Settings

Demand window length

The determination of demand can vary by utility. Some utilities use the peak instantaneous demand measured but most use a fifteen minute average demand or a one hour average demand. Some gas utilities measure demand as the use during the peak day or peak week.

The choices for demand window are:

- QuarterHour
- HalfHour
- FullHour
- Day
- Week

This field is defaulted to the shortest QuarterHour.

Note: The choice may be overridden based on the value of simulation time step so that they are consistent, i.e. demand window length should be exact multiples of simulation time step length in minute. For example, if the time step is 6, i.e. 10 minutes time step, then QuarterHour is not used and instead HalfHour is used. Or if time step is 3, i.e. 20 minutes time step, then QuarterHour and HalfHour are not used and instead FullHour is used.

Use 'Real time pricing charge schedule'?

Check this checkbox if you would like to use a real time pricing schedule (below).

Real time pricing charge schedule

This field is used with real time pricing rates. The schedule contains the cost of energy for that particular time period of the year. Real time rates can be modelled using a charge schedule with the actual real time prices entered. The charges should be consistent with the conversion factor specified in the tariff.

When this option is enabled, the Time of Use Period, Season and Month schedules are not needed unless Charge objects are used in defining other charges which involve these schedules.

Use 'Customer baseline load schedule'?

Check this checkbox if you would like to use a Customer baseline load schedule (below).

Customer baseline load schedule

Customer baseline load (CBL) schedule is used with real time pricing rates. This field provides the name of a schedule that contains the baseline energy use for the customer. Many real time rates apply the charges as a

credit or debit only to the difference between the baseline use and the actual use. The baseline use is established between the customer and the utility using a contract.

If this field is used the baseline totalEnergy and totalDemand is calculated, then compared to the metered value and therefore the real time rate charge based on the difference is calculated using the values defined in real time pricing charge schedule, which is either added or subtracted to the utility cost.

If this field is not used, the real time charge schedule applies to all energy from the meter and totalEnergy and totalDemand is based on metered value as usual.

Use 'Group name'?

Check this checkbox if you would like to use a Group name (below).

Group name

This field defines the group name of the tariff such as distribution, transmission, supplier, etc. If more than one tariff with the same group name is present and qualifies, only the lowest cost tariff is used. Usually the group name field is left blank which results in all tariffs using the same meter variable being compared and the lowest cost one being selected.

Monthly service charge

This gives a fixed monthly service charge that many utilities have. The entry may be numeric and gets added to the ServiceCharges variable. The entry can also be a variable name, where the values for each month will be used (this variable must be defined on 'User Variables' tab).

Minimum monthly charge

The minimum total charge for the tariff or if a variable name is entered here, its values for each month are used (the variable must be defined on 'User Variables' tab). The sum of the Subtotal and Taxes usually equals the total unless you have specified the minimum monthly charge and it is greater than the sum of the Subtotal and Taxes.

Buy or sell

It sets whether the tariff is used for buying, selling or both to the utility. This should be allowed to default to BuyFromUtility unless a power generation system is included in the building that may generate more power than the building needs during the year.

The choices are:

- BuyFromUtility – The values from the metered variable are used and are shown as being purchases from the utility.
- SellToUtility – The values from the metered variable are used for a "sell back" rate to the utility. The charges in the rate should be expressed as negative values.
- NetMetering – Negative values are used to reduce any positive values during the specific period on the tariff when negative values occur (sell back to utility).

A warning will be issued if the selection of this field does not match the type of meter (please refer to Output Meter Name field for more details).

Tariff Analysis - Charge Tab

Charge tab on [Tariff Analysis](#) dialog

Charge Selection

Number of charges

The number of charges applied in this tariff can be selected from this dropdown list.

Simple or Block?

Select the charge type according to utility rate settings from:

- **1-Simple** is used to compute energy and demand charges that are very simple. It may also be used for taxes, surcharges and any other charges that occur on a utility bill. As many Simple Charge objects as needed may be defined for a single tariff and they will be added together.
- **2-Block** is used to compute energy and demand charges that are structured in blocks of charges. It may also be used for Taxes, Surcharges and any other charges that occur on a utility bill, although those are more commonly simple flat charges, so Simple Charge is more commonly used for those functions. As many Block Charge objects as needed may be defined for a single tariff and they will be added together. Blocks are a structure used by most utilities for calculating energy and demand charges and they allow the utility to charge more or less per unit of energy or demand if more units are used.

Charge : Simple

Charge variable name

This is the name associated with the Simple charge object and will appear in the report, which is also used to store the results of the Simple charge calculation. Spaces are not significant in Charge variable names. They are removed during the utility bill calculation process.

Source variable

This is the name of the source used by the Simple charge. This is usually the name of the variable holding the energy or demand but may also be the name of any variable including the Subtotal or Basis if other charges are based on those. This should be typed exact as defined.

the Source variable is usually the name of the variable holding the energy or demand but may also be the name of any variable including the subtotal or basis if other charges are based on those.

The list of EnergyPlus pre-defined variable names is:

- totalEnergy
- totalDemand
- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustments
- Surcharges
- Subtotal
- Taxes
- Total

If it is a time-of-use rate then:

- peakEnergy
- peakDemand
- shoulderEnergy
- shoulderDemand
- offPeakEnergy

- offPeakDemand
- midPeakEnergy
- midPeakDemand

In addition see the Tariff Report in the [Summary](#) output to see other native variables that may be available.

Also you can create additional user defined variables to model complex tariffs.

Season

This is the name (or number) of a season for which the Simple charge is calculated. If this is set to Annual, the calculations are performed for the entire year (all months), otherwise they are calculated only for the months in the season defined. The season is defined by the Season Schedule on the Tariff tab.

The choices for seasons are the following:

- **1-Annual**
- **2-Winter**
- **3-Spring**
- **4-Summer**
- **5-Fall/Autumn**

Category variable name

Charges are added in the hierarchy as described on [Tariff Analysis](#) page. This field shows where the charge should be added. The reason for entering this field appropriately is to get the charge reported in a reasonable category. The charge automatically gets added to the variable named after this category. The choices for this field are limited to:

- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustment
- Surcharge
- Subtotal
- Taxes
- Total
- NotIncluded

Cost per unit value or variable name

This field contains either a single number or the name of a variable. The number is multiplied with all of the energy or demand or other source that is specified in the source field. If a variable is used, then the monthly values of the variable are multiplied against the variable specified in the source field (the variable should be defined on the [User variables](#) tab). If no value or variable is entered, a zero is assumed. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

Charge : Block

Block charges are used extensively for tariff calculation. They are used to compute energy and demand charges that are structured in blocks of charges. They may also be used for taxes, surcharges and any other charges that occur on a utility bill but those are more commonly simple flat charges so Charge:Simple is more commonly used for those functions. As many Charge Blocks as needed may be defined for a single tariff and they will be added together. Blocks are a structure used by most utilities for calculating energy and demand charges and they allow the utility to charge more or less per unit of energy or demand if more units are used.

Charge variable name

This is the name associated with the Block charge object and will appear in the report, which is also used to store the results of the Block charge calculation. Spaces are not significant in Charge variable names. They are removed during the utility bill calculation process.

Source variable

This is the name of the source used by the Block charge. This is usually the name of the variable holding the energy or demand but may also be the name of any variable including the Subtotal or Basis if other charges are based on those. This should be typed exact as defined.

Season

This is the name (or number) of a season for which the Block charge is calculated. If this is set to Annual, the calculations are performed for the entire year (all months), otherwise they are calculated only for the months in the season defined. The season is defined by the [Season schedule](#) on the Tariff tab.

The choices for seasons are the following:

- **1-Annual**
- **2-Winter**
- **3-Spring**
- **4-Summer**
- **5-Fall/Autumn**

Category variable name

Charges are added in the hierarchy as described on [Tariff Analysis](#) page. This field shows where the charge should be added. The reason for entering this field appropriately is to get the charge reported in a reasonable category. The charge automatically gets added to the variable named after this category. The choices for this field are limited to:

- EnergyCharges
- DemandCharges
- ServiceCharges
- Basis
- Adjustment
- Surcharge
- Subtotal
- Taxes
- Total
- NotIncluded

Remaining into variable

If the blocks do not use all of the energy or demand from the source, some energy and demand remains, then the remaining amount should be assigned to a variable. If no variable is assigned and some amount of energy or demand is not used in the block structure a warning will be issued.

Block size multiplier value or variable name

The sizes of the blocks are usually used directly but if a value or a variable is entered below, the block sizes entered in the rest of the charge are first multiplied by the entered value prior to being used. This is common for rates that are kWh/kW rates and in that case the variable that holds the monthly total electric demand would be entered.

Block size multiplier or variable name > Use value or variable name

Select whether you wish to use a value or variable to define a multiplier to be applied to all energy or demand or other source that is specified in the source field. Select from:

- **1-Value** - where all of the energy or demand or other source that is specified in the source field are multiplied by this value.
- **2-Variable name** where the monthly values of the variable are multiplied by the variable specified in the source field (the variable should be defined on “User Variables” tab).

If a variable is used, then the monthly values of the variable are multiplied against the variable specified in the source field (the variable should be defined on “User Variables” tab). If no value or variable is entered, a zero is assumed. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

Block size multiplier or variable name > Input multiplier value

When [Use value or variable name](#) is set to **1-Value**, enter the multiplier value to be used to multiply the source data (e.g. energy demand).

Block size multiplier or variable name > Input multiplier variable name

When [Use value or variable name](#) is set to **2-Variable name**, enter the name of the variable that defines the multiplier, e.g. **totalDemand**.

See: [EnergyPlus Example E – kWh/kW Energy Charges](#) for an example of how to use this setting.

Number of blocks

Select the number of blocks needed for this Block charge setting.

Block size 1 value

The size of the first block of the charges is entered here. For most rates that use multiple blocks, this will be the value for the first block size. Additional block sizes are entered with every other field.

Block 1 cost per unit value

The cost per unit value of the first block is entered here. This value is also repeated for every other field in the charge when required. As many blocks may be entered as are needed. For SellToUtility tariffs, the values in this field are usually expressed as negative numbers.

Note: The above two fields run as a group can be repeated many times up to the number defined in [Number of blocks](#) field. For the last pair of the two, a default variable named **remaining** represents a very large value which may be used when the remaining amount should be included in that block. This **remaining** is EnergyPlus reserved keyword.

Tariff Analysis - Qualify Tab

Qualify tab on [Tariff Analysis](#) dialog

Many utilities provide a large number of tariffs and separate their customers by their energy use or by the peak demand. The Qualify object allows only certain tariffs that are modelled to be used. If the results of the simulation fall outside of the range of qualifications, that tariff is still calculated but in the results the “Qualified” entry will say “No” and the Qualify object that caused its exclusion is shown. Multiple tariffs from the same utility can be modelled and only one of them should be used, make sure that the qualifiers are consistent especially within the same [Group name](#) (defined on the [Tariff](#) tab). Multiple Qualify objects can appear for a specific rate and they can be based on any variable.

The energy used and demands for each month vary. Since it is possible that they vary across the minimum and maximum values defined by this object, a choice in how to treat the thresholds is necessary. Utilities

typically have specific requirements about which months or consecutive months can be above or below a threshold to qualify for the rate.

Number of qualify checks

The number of qualify checks for this tariff is defined here.

Name

The name used for the Qualify object and displayed if the tariff qualify or does not qualify. It is also treated as a variable and contains:

- 1 for each month that does qualify,
- 0 for months that do not qualify, and
- -1 for months that are not part of the season selected.

Variable name

The name of the variable used. For energy and demand, the automatically created variables, totalEnergy and totalDemand should be used, respectively.

Qualify type

This defines criteria for checking tariff's qualification, the options can be either "Minimum" or "Maximum".

Threshold value or variable name

This is the minimum or maximum value set for the qualify check. If the variable has values that are less than this value when the qualify type is minimum then the tariff may be disqualified. If the variable has values that are greater than this value when the qualify type is maximum then the tariff may be disqualified. Depending on the threshold test entry (see below) this threshold value applies to all months, some of the months or just a single month. If a variable that contains this threshold values is used, it should be defined on [User Variables](#) tab.

Season

If the UtilityCost:Qualify only applies to a season, enter the season name from the following list:

- Annual
- Winter
- Spring
- Summer
- Fall (Autumn)

It defaults to Annual.

Threshold test

The **Number of months** (below) is used in one of two different ways depending on this setting. Select from:

- **1-Count** where the qualification is based on the count of the total number of months per year.
- **2-Consecutive** where the qualification is based on a consecutive number of months.

Input Number of months

Check this checkbox if you would like to enter the number of months.

Number of months

A number is used here from 1 to 12. If **Input Number of months** is not checked, 12 is assumed when the qualify type is minimum and 1 when the qualify type is maximum. This is the number of months that the threshold test applies to determine if the rate qualifies or not. If the season is less than 12 months (if it is not annual) then the value is automatically reduced to the number of months of the season.

Tariff Analysis - Ratchet Tab

Ratchet tab on [Tariff Analysis](#) dialog

Ratchets are commonly used by US utility tariffs for large commercial and industrial electricity customers as a mechanism to calculate the demand charges on monthly electricity bills. They may be used to ensure that a high demand spike in one month, or season, results in a minimum billing charge for several subsequent months, even if the customer's actual usage is lower.

Utilities charge customers based on two main components:

- **Energy Charge** (kWh): the total amount of electricity consumed over the billing period.
- **Demand Charge** (kW): The maximum rate at which electricity was used during a short interval within the billing period.

A ratchet is a clause in the tariff that links the demand charge for the current month to a high demand peak from a previous month or season. A typical demand ratchet determines the Billed Demand (kW amount the customer is charged for) as the greater of:

1. The actual maximum demand in the current billing month.
2. A percentage (often 50% to 90%) of the highest maximum demand in a specified "look-back" period (e.g., the previous 11 months, or the peak summer season).

Why Utilities Use Ratchets

A utility must design its infrastructure (generators, transformers, transmission lines) to handle the maximum demand of all its customers. Even if a customer only hits a high peak once a year, the utility still has to build and maintain the capacity to serve that spike year-round. Utilities use ratchets to ensure they can recover the costs of building and maintaining a reliable electricity grid, especially the capacity required to serve peak loads. Ratchets create a strong financial incentive for large customers to avoid or manage short, excessive spikes in power usage, thereby smoothing out the load on the grid and deferring the need for costly infrastructure upgrades.

Ratchet Example 1

Consider a tariff has a ratchet set at 80% of the highest peak demand in the previous 11 months.

- **January:** The customer uses its equipment heavily and hits a peak demand of 1,000 kW. This sets a new high mark.
- **February - December (Next 11 Months):**
 - The ratchet "locks in" a minimum billed demand of 80% of that \$1,000 kW peak, which is 800 kW.
 - If the actual maximum demand in any of these months is 500 kW, you will still be charged for the minimum ratchet amount of 800 kW.
 - If your actual maximum demand in a later month is 900 kW, which is higher than the ratchet minimum, you will be charged for the actual demand of 900 kW (and this new high may reset the ratchet minimum for the remaining months).

The effect is that one brief surge in energy use can determine the minimum demand charge you pay for nearly a full year.

Ratchet Example 2

A utility has a single ratchet that says that the billing demand for each month of the year is the higher value of the actual demand or 60% of the peak summer demand.

DesignBuilder input:

Ratchet	
How many ratchets applied?	1
Ratchet 1 settings	
Ratchet variable name	BillingDemand1
Baseline source variable	TotalDemand
Adjustment source variable	TotalDemand
Season from	4-Summer
Season to	1-Annual
Multiplier value or variable name	
Use value or variable name?	1-Value
Input multiplier value	0.60
Offset value or variable name	
Use value or variable name?	1-Value
Input offset value	0.00

EnergyPlus idf:

```

    BillingDemand1,      ! Ratchet Variable Name
    ExampleTariff1,     ! Tariff Name
    TotalDemand,        ! Baseline Source Variable
    TotalDemand,        ! Adjustment Source Variable
    Summer,             ! Season From
    Annual,             ! Season To
    0.60,               ! Multiplier Value or Variable Name
    0;                  ! Offset Value or Variable Name
```

Multiple Ratchets

Multiple ratchets may be used to manage different peak concerns - like summer heat vs. year-round capacity - and they are applied sequentially to ensure the billed demand reflects the highest possible charge across all rules.

When a utility tariff contains multiple demand ratchets, they are applied in a chain or sequence. The goal is to compare the maximum demand from different look-back periods and different rules, and ultimately select the highest result as the customer's final Billed Demand. The mechanics are as follows:

1. **Ratchet 1 (e.g., Annual Ratchet):** The calculation for the first ratchet is performed, comparing the current month's peak to the highest peak in the previous 11 months (or the year).¹ The higher of these two values becomes the interim Billed Demand, let's call it D_1 .
2. **Ratchet 2 (e.g., Seasonal Ratchet):** The calculation for the second ratchet is performed. This ratchet often compares a seasonal peak (like the highest summer peak) to the current month's demand. The Billed Demand from Ratchet 1 (D_1) is used as the starting value or baseline for this comparison.

Final Billed Demand = Greater of (D_1 OR a percentage of the highest kW peak during the last peak season).

Essentially, the output of the first ratchet is fed into the second, and the output of the second is fed into the third (if one exists). This layering guarantees the customer pays a demand charge based on the worst-case scenario (highest demand spike) as defined by any of the tariff's ratchet rules.

In DesignBuilder, if multiple ratchets occur in the same tariff, they can be "chained" together using the [Baseline source variable](#) replaced with the [Ratchet variable name](#) of the previous Ratchet.

Chained Example

A large commercial customer might have two ratchets:

- **Rule A (Annual):** Billed Demand is the greater of (Current Month kW OR 80% of the last 11 months' highest kW)
- **Rule B (Seasonal):** Billed Demand is the greater of (Current Month kW OR 90% of the highest kW peak during the previous Summer season).

The final demand is the highest result derived from both comparisons.

When Utilities Use Multiple Ratchets

Utilities employ multiple, chained ratchets when they need to recover costs that are driven by different factors at different times of the year.

1. Separating Seasonal vs. Annual Capacity Costs

The most common reason for using multiple ratchets is to distinguish between costs related to annual operations and costs related to seasonal stress on the grid.

- **Seasonal Peak Ratchet (90% Summer Rule):** This rule is designed to recover the cost of peaking generation and transmission/distribution upgrades needed specifically to handle the extreme load of the hottest summer days (high air conditioning use). The high summer demand sets a high minimum for several non-summer months.
- **Annual Ratchet (80% Rolling Rule):** This rule ensures recovery of costs for the base, fixed capacity that must be available year-round, regardless of the season.

2. Targeting Coincident vs. Non-Coincident Peaks

Some utilities use multiple ratchets to separate charges for:

- **Non-Coincident Peak (NCP):** The customer's absolute highest kW peak for the month, regardless of when it occurs.
- **Coincident Peak (CP):** The customer's kW demand measured at the exact same time as the utility's entire system hit its highest overall peak (the "system peak").

A complex tariff might use a ratchet for the NCP and a separate, chained ratchet for the CP, ensuring the customer is incentivised to lower their usage during both their individual peak and the grid's most stressed hours.

Ratchet

Ratchet variable name

This entry defines the name of the ratchet and the variable that stores the result of this ratchet. The ratchet variable name should be used wherever the ratchet should be applied and is often the source variable for Simple or Block charge objects.

Baseline source variable

The name of the variable used as the baseline value. When the ratcheted value exceeds the baseline value for a month the ratcheted value is used but when the baseline value is greater than the ratcheted value the baseline value is used. Usually the electric demand charge is used. The baseline source variable can be the results of another ratchet object. This allows utility tariffs that have multiple ratchets to be modelled.

Adjustment source variable

This field defines the variable that the ratchet is calculated from. It is often but not always the same as the baseline source variable. The ratcheting calculations using offset and multiplier are using the values from the adjustment source variable. See the bottom of this section for how ratchet works.

Season from

This is the name of the season that is being examined. The maximum value for all of the months in the named season is what is used with the multiplier and offset. This is most commonly Summer or Annual. When Monthly is used, the adjustment source variable is used directly for all months.

The choices are:

- Annual
- Winter
- Spring
- Summer
- Fall (Autumn)
- Monthly

Season to

This is the name of the season when the ratchet would apply. This is most commonly Winter. The ratchet only is applied to the months in the named season. The resulting variable for months not in the Season To selection will contain the values as appear in the baseline source variable. The choices are:

- Annual
- Winter
- Spring
- Summer
- Fall (Autumn)

Multiplier value or variable name

Often the ratchet has a clause such as “the current month demand or 90% of the summer month demand”. For this case a value of 0.9 would be entered here as the multiplier. This value may be given as one if no multiplier is needed. This can also be a variable name, which should be defined on [User variables](#) tab.

Offset value or variable name

A less common strategy is to say that the ratchet must be all demand greater than a value, in this case an offset that is added to the demand may be entered here. If entered, it is common for the offset value to be negative representing that the demand be reduced. The value can be zero if not offset is needed in the ratchet. This can also be a variable name, which should be defined on [User variables](#) tab.

Detailed step taken for ratchet calculation

- AdjSeasonal contains either:
 - When SeasonFrom is not set to Monthly, the maximum for all months in Season From in the Adjustment Source Variable. This is a single value.
 - When SeasonFrom is set to Monthly, the monthly values of the Adjustment Source Variable.
- $\text{AdjPeak} = (\text{AdjSeasonal} + \text{Offset}) * \text{Multiplier}$
- MaxAdjBase = maximum value of either AdjPeak or Baseline Source Variable
- The resulting Ratchet Variable contains:
 - For months not in SeasonTo, the values of Baseline Source Variable
 - For months in SeasonTo, the values of MaxAdjBase

For a simple typical case using totalDemand for both “Baseline source variable” and “Adjustment source variable”, please see the example at the top of this page.

Tariff Analysis - User Variables Tab

User variables tab on [Tariff Analysis](#) dialog

This tab defines and stores any user defined variables required for selection on other tabs of this dialog. Monthly values can be entered for each variable.

Note: Variables are defined using a text name which must be entered exactly on the previous tabs to match with the variable defined here.

The places on the other Tariff analysis dialog tabs where a variable can be entered are:

Tariff tab

- [Monthly service charge](#) variable name
- [Minimum monthly charge](#) variable name

Charge tab

- [Charge](#) variable name (Simple Charge setting)
- [Charge](#) variable name (Block Charge setting)

Qualify tab

- [Threshold](#) variable name

Ratchet tab

- [Multiplier](#) variable name
- [Offset](#) variable name

Variables Used

Number of variables used

Enter the number of variables to be defined.

Variable N Settings

For each variable enter the following data.

Name

This field defines the name of the variable.

Variable type

This field is used to indicate the kind of units that may be associated with the variable. It is used by IDF Editor to display the appropriate SI and IP units for the January through December values. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- Energy
- Demand
- Currency
- Dimensionless

January Through December Values

January value

February value

...

December value

Each field contains an entry of the monthly values of the variable. Normally 12 months are used for most utility rates and so 12 values should be entered.

Tariff Examples

One of the best ways to learn the details of EnergyPlus Economics and how to calculate operational energy costs is to study some example tariffs and how they are entered on the Tariff dialog. The examples below illustrate the process of setting up various tariffs for a range of cases of increasing complexity. Each example includes a description of the tariff to be modelled, step-by-step instructions on how to define it and sample summary output showing the corresponding EnergyPlus economics reports.

Note: The examples provided below are based on entering costs in US Dollars (USD/\$), but the principles are the same for all currencies. The [Currency](#) can be selected on the [International](#) tab of the Program options dialog.

List Of Examples

- [Create Base Model - Optional Preliminary Steps for Examples A-I](#)
- [Example A – Flat Energy Charge](#)
- [Example B – Block Energy Charge](#)
- [Example C – Block Energy and Demand Charges](#)

- [Example D - Seasonal Energy Charges with Minimum Charge](#)
- [Example E – kWh/kW Energy Charges](#)
- [Example F – Seasonal Time of Use Energy](#)
- [Example G – Blocks within Blocks](#)
- [Example H – Real Time Pricing](#)
- [Example I – Selling and Net-Metering](#)
- [Example J - Dual Ratchet Demand Tariff](#)

Create Base Model - Optional Preliminary Steps For Examples A-J

The tariffs described below under Examples A-J headings can be set up for any model. However, if you would like to reproduce the summary results provided to aid your learning process, you should apply the tariffs to the same base model used to create the results below. You can create the base model by following the steps below.

1. Create a new file located in London Gatwick and add a building to the site with a simple rectangular block having dimensions 20m x 10m as shown below. Start by using default Model options and template settings.
2. Set the [Detailed HVAC](#) model option. This is a required step as EnergyPlus Economics only works with full HVAC system definitions.
3. Load the default "FCU 4-pipe, Air-cooled Chiller" Detailed HVAC template.
4. Add a [PV panel](#) on the roof with dimensions 10m x 3m and rotate it so it faces south with an inclination of 45°.
5. Connect the PV panel to a distribution centre. To do this, go to the [Generation tab](#), create a new [Load centre](#) by copying the existing default "DC with Inverter" library load centre. On the **Generator List** tab, select your Solar collector.

The PV panel will be used in [Example I](#) to illustrate "net metering" and cases where electricity is sold back to the utility.

The model should now look similar to the screenshot below.

Example A – Flat Energy Charge

This example shows how to define a simple tariff which charges for electricity at a constant rate with a fixed monthly service fee. This simple approach is suitable for utilities or contracts that charge a flat rate without tiered pricing or demand charges.

- Customer charge: \$2.51 per month
- Energy charge: 5.5342 cents/kWh

This simple tariff can be set up by making the following settings on the Economics tab at building level.

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

The screenshot shows the 'Tariffs' dialog box. The 'Include tariff analysis' checkbox is checked. The 'Number of tariffs' is set to 1. Below this, 'Tariff 1' is listed with the name 'EnergyPlus Example A - Flat Energy Charge'.

2. On the **Tariff** tab of the Tariff dialog, set the fixed monthly fee to \$2.51 per month using the [Input monthly service charge value](#) setting as shown below:

The screenshot shows the 'Tariffs' dialog box with the 'Tariff' tab selected. The 'Tariff name' is 'EnergyPlus Example A - Flat Energy Charge'. The 'Description' is 'Example data'. The 'Source' is empty. The 'Category' is 'Electricity tariffs'. The 'Output meter name' is '1-Electricity:Facility'. The 'Conversion factor choice' is '2-kWh'. The 'Schedules' section has three unchecked checkboxes: 'Use 'Time of use period schedule'', 'Use 'Season schedule'', and 'Use 'Month schedule''. The 'Other Settings' section has four unchecked checkboxes: 'Demand window length' (set to '1-QuarterHour'), 'Use 'Real time pricing charge schedule'', 'Use 'Customer baseline load schedule'', and 'Use 'Group name''. The 'Monthly service charge' section has 'Monthly service charge or variable name' set to '1-Charge value' and 'Input monthly service charge value (USD)' set to '2.51'. The 'Minimum monthly charge' section has 'Minimum monthly charge or variable name' set to '1-Charge value' and 'Input minimum monthly charge value (USD)' set to '0.0000'. The 'Buy or Sell' section has 'Buy or Sell' set to '1-buyFromUtility'.

3. On the **Charge** tab:

- Set the Number of charges to 1.

- Under the **Charge 1 settings** header:
 - Set [Simple or Block?](#) to **1-Simple**.
 - Set the [Input cost per unit value](#) to 0.055342 USD:

Example B – Block Energy Charge

This example adds tiered energy pricing blocks to a flat fee, where cost decreases as consumption increases. This is common for residential or small commercial tariffs with step-down pricing to make higher usage rates more affordable.

- Customer charge: \$5.75 per month
- Energy charges:
 - o 7.231 cents/kWh for first 200 kWh
 - o 6.656 cents/kWh for next 1000 kWh
 - o 5.876 cents/kWh for over 1200 kWh

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

The screenshot shows the 'Tariffs' dialog box. The 'Include tariff analysis' checkbox is checked. The 'Number of tariffs' is set to 1. The 'Tariff 1' dropdown shows 'EnergyPlus Example B - Block Energy Charge'.

2. On the **Tariff** tab of the Tariff dialog:

- Set the fixed monthly fee to \$5.75 per month using the [Input monthly service charge value](#) setting as shown below:

The screenshot shows the 'Tariffs' dialog box, 'Tariff' tab. The 'General' section is expanded, showing the 'Tariff name' as 'EnergyPlus Example B - Block Energy Charge'. The 'Monthly service charge' is set to 5.7500. The 'Charge' tab is also visible.

3. On the **Charge** tab:

- Set the Number of charges to 1.
- Under the **Charge 1 settings** header:
 - Set [Simple or Block?](#) to **2-Block**
 - Set [Source variable](#) to **totalEnergy**
 - Set the [Number of blocks](#) to 3
 - Set [Block size 1 value](#) to 200.
 - Set [Block 1 cost per unit value](#) to 0.07231 USD.
 - Set [Block size 2 value](#) to 1000.
 - Set the [Block 2 cost per unit value](#) to 0.06656 USD.
 - Set the [Block size 3 variable name](#) to **remaining**.
 - Set the [Block 3 cost per unit value](#) to 0.05876 USD.

The screenshot below show how the charge tab should look when you have finished.

Example C – Block Energy And Demand Charges

This example uses separate block structures for energy and demand charges. This approach is suitable for modelling commercial tariffs that include both consumption and peak demand billing components. Demand charges encourage customers to manage their peak usage patterns, not just total consumption. It is similar to the previous example except it includes demand charges as well. The energy and demand charges vary by the amount of energy and demand consumed each month.

- Energy charges:
 - o 4.74 cents/kWh for first 20,000 kWh
 - o 4.24 cents/kWh for next 180,000 kWh
 - o 3.83 cents/kWh for additional kWh
- Demand charges:
 - o 5.38 dollars per kW for first 20 kW
 - o 4.23 dollars per kW for next 80 kW
 - o 3.60 dollars per kW for additional kW

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

Tariffs

☒ Include tariff analysis

Number of tariffs: 1

Tariff 1: EnergyPlus Example C - Block Energy and Demand Char

2. On the **Tariff** tab of the Tariff dialog, clear any fixed tariff data as shown below:

Tariffs

Tariff

Schedules

☐ Use 'Time of use period schedule'?
☐ Use 'Season schedule'?
☐ Use 'Month schedule'?

Other Settings

Demand window length
1-QuarterHour

☐ Use 'Real time pricing charge schedule'?
☐ Use 'Customer baseline load schedule'?
☐ Use 'Group name'?

Monthly service charge

Monthly service charge or variable name
1-Charge value

Input monthly service charge value (USD)
0.0000

Minimum monthly charge

Minimum monthly charge or variable name
1-Charge value

Input minimum monthly charge value (USD)
0.0000

Buy or Sell

Buy or Sell
1-buyFromUtility

3. On the **Charge** tab:

- Set the [Number of charges](#) to 2, the first covering energy, the other for demand.
- Under the **Charge 1 settings** header:
 - Set [Simple or Block?](#) to **2-Block**.
 - Set [Charge variable name](#) to **BlockEnergyCharge**
 - Set [Source variable](#) to **totalEnergy**
 - Set the [Number of blocks](#) to 3
 - Set [Block size 1 value](#) to 20,000.
 - Set [Block 1 cost per unit value](#) to 0.0474 USD.
 - Set [Block size 2 value](#) to 180,000.
 - Set the [Block 2 cost per unit value](#) to 0.0424 USD.
 - Set the [Block size 3 variable name](#) to **remaining**.
 - Set the [Block 3 cost per unit value](#) to 0.0383 USD.
- Under the **Charge 2 settings** header:
 - Set [Simple or Block?](#) to **2-Block**.
 - Set [Charge variable name](#) to **BlockDemandCharge**
 - Set [Source variable](#) to **totalDemand**
 - Set [Category variable name](#) to **2-DemandCharges**
 - Set the [Number of blocks](#) to 3
 - Set [Block size 1 value](#) to 20.
 - Set [Block 1 cost per unit value](#) to 5.38 USD.
 - Set [Block size 2 value](#) to 80.
 - Set the [Block 2 cost per unit value](#) to 4.23 USD.
 - Set the [Block size 3 variable name](#) to **remaining**.
 - Set the [Block 3 cost per unit value](#) to 3.60 USD.

The screenshot below show how the charge tab should look when you have finished.

Example D - Seasonal Energy Charges With Minimum Charge

Utilities often have higher rates during peak seasons and minimum monthly charges to cover fixed costs. This example applies different block rates by season plus a minimum monthly fee. It is suitable for utilities with seasonal block structures (winter vs summer) and a guaranteed minimum bill.

- Minimum charge: \$7.00 per month
- Winter – October through May, energy charges:
 - 4.385 cents/kWh for first 650 kWh
 - 3.763 cents/kWh for next 350 kWh
 - 3.704 cents/kWh for over 1000 kWh
- Summer – June through September, energy charges:
 - 8.385 cents/kWh for first 650 kWh
 - 7.588 cents/kWh for next 350 kWh
 - 7.103 cents/kWh for over 1000 kWh

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

2. On the **Tariff** tab of the Tariff dialog:

- Set the fixed monthly fee to \$7.00 per month using the [Input monthly service charge value](#) setting.
- Check the [Use 'Season schedule'](#) checkbox to reveal the Season schedule setting.
- Create a new [Seasonal schedule](#) by copying the "Two season schedule (Northern Hemisphere)" library schedule. Call the new schedule "Two season schedule". The library schedule already contains the right settings, so for this example, no further changes are needed to the copy. But for other definitions of summer (e.g. in the Southern hemisphere) you should make the necessary edits to the copied schedule.
- Select the newly created Seasonal schedule.

The Tariff tab should now look similar to the screenshot below.

3. On the **Charge** tab:

- Set the [Number of charges](#) to 2, the first covering winter, the other for summer.
- Under the **Charge 1 settings** header:
 - Set [Simple or Block?](#) to **2-Block**.
 - Set [Charge variable name](#) to **WinterEnergyCost**
 - Set [Source variable](#) to **totalEnergy**
 - Set [Season](#) to **2-Winter**.
 - Set the [Number of blocks](#) to 3
 - Set [Block size 1 value](#) to 650.
 - Set [Block 1 cost per unit value](#) to 0.04385 USD.
 - Set [Block size 2 value](#) to 350.

- o Set the [Block 2 cost per unit value](#) to 0.03763 USD.
- o Set the [Block size 3 variable name](#) to **remaining**.
- o Set the [Block 3 cost per unit value](#) to 0.03704 USD.
- Under the **Charge 2 settings** header:
 - o Set [Simple or Block?](#) to **2-Block**.
 - o Set [Charge variable name](#) to **SummerEnergyCost**
 - o Set [Source variable](#) to **totalEnergy**
 - o Set [Season](#) to **4-Summer**.
 - o Set the [Number of blocks](#) to 3
 - o Set [Block size 1 value](#) to 650.
 - o Set [Block 1 cost per unit value](#) to 0.08385 USD.
 - o Set [Block size 2 value](#) to 350.
 - o Set the [Block 2 cost per unit value](#) to 0.07588 USD.
 - o Set the [Block size 3 variable name](#) to **remaining**.
 - o Set the [Block 3 cost per unit value](#) to 0.07103 USD.

The screenshot below show how the charge tab should look when you have finished.

Example E – KWh/kW Energy Charges

This example shows how to model a more sophisticated rate structure which encourages efficient energy use by linking energy pricing to monthly demand levels. Higher load factors (more consistent energy use) receive better rates. Energy blocks are multiplied by monthly peak demand to reflect load factor incentives. Such tariffs may be offered when customers with consistent energy use are more cost-effective to serve.

- Customer charge: \$14.00 per month
- Energy charges:
 - o 8.756 cents/kWh for all consumption not greater than 200 hours times the demand
 - o 6.812 cents/kWh for all consumption in excess of 200 hours and not greater than 400 hours times the demand
 - o 5.029 cents/kWh for all consumption in excess of 400 hours times the demand.

This tariff uses a single Charge object. The monthly charge is defined on the Tariff tab. In this case the Block size multiplier is set to the **totalDemand** variable.

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

Tariffs

☒ Include tariff analysis

Number of tariffs

1

Tariff 1

EnergyPlus Example E - kWh per kW Energy Charges

2. On the **Tariff** tab of the Tariff dialog:

- Set the fixed monthly fee to \$14.00 per month using the [Input monthly service charge value](#) setting.

The Tariff tab should now look similar to the screenshot below:

Example F – Seasonal Time Of Use Energy

Utilities face different costs throughout the day and year. Time-of-use rates pass these cost variations on to customers, encouraging usage during low-cost periods and discouraging use during high-cost periods. For example, tariffs sometimes have higher costs for energy consumed during the daytime than at night. In this example, four simple rates combine to create on-peak/off-peak and summer/winter distinctions. This approach is suitable for time-of-use tariffs where rates vary by both season and time of day.

- Monthly charge: \$37.75 per month
- Winter – October through May
 - o On Peak: 8.315 cents/kWh
 - o Off-Peak: 2.420 cents/kWh
- Summer – June through September
 - o On Peak: 14.009 cents/kWh
 - o Off-Peak: 6.312 cents/kWh

The on-peak period is defined as the hours starting at 10am and ending at 7pm, Monday through Friday for June through September and 3pm to 10pm Monday through Friday for October through May. All other hours are considered off-peak.

The tariff is only applicable for customers that use 50KW for at least one month of the year. This restriction is implemented by entering details on the Qualify tab.

This tariff uses four different Charge:Simple objects to capture the variation of energy cost with time.

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

Tariffs

☒ Include tariff analysis

Number of tariffs: 1

Tariff 1: EnergyPlus Example F - Seasonal Time of Use Energy

2. On the **Tariff** tab of the Tariff dialog:

- Set the fixed monthly fee to \$37.75 per month using the [Input monthly service charge value](#) setting.
- Check the [Use 'Time of use period schedule'?](#) checkbox.
- Use the [Time of use period schedule](#), to define the on peak and off peak times. You can base your schedule on the library "Time of day schedule" by copying it, renaming the new schedule "TimeOfDaySchedule" and making any changes needed. As it happens the schedule shouldn't need any changes. It should look like the screenshot below.

Edit schedule - TimeOfDaySchedule

Schedules

Through: 31 Dec,
For: AllDays,
Until: 15:00, 3,
Until: 22:00, 1,
Until: 24:00, 3;

- Check the [Use 'Season schedule'](#) checkbox to reveal the Season schedule setting.
- Create a new [Seasonal schedule](#) by copying the "Two season schedule (Northern Hemisphere)" library schedule. Call the new schedule "Two season schedule". The library schedule already contains the right settings, so for this example, no further changes are needed to the copy. But for other definitions of summer (e.g. in the Southern hemisphere) you should make the necessary edits to the copied schedule.
- Select the newly created Seasonal schedule.

The Tariff tab should now look similar to the screenshot below:

Tariffs

Example G – Blocks Within Blocks

Some utilities create complex rate structures that combine load factor incentives with traditional tiered pricing. This requires nested block calculations. Example G shows how to implement nested block structures by first allocating a demand-scaled block, then applying standard blocks to the resulting subsets. It is suitable for modelling complex tariffs combining scaled demand blocks and traditional kWh tiers for advanced load factor management.

- Monthly charge: \$35 per month
- Energy charges:
 - For all consumption not greater than 200 hours times the demand use:
 - o 10.32 cents/kWh for the first 1000 kWh
 - o 7.43 cents/kWh for the next 4000 kWh
 - o 6.23 cents/kWh for the next 5000 kWh
 - o 4.27 cents/kWh for the remaining kWh less than 200 hours times the demand
 - For all consumption in excess of 200 hours and not greater than 400 hours times the demand, use:
 - o 6.82 cents/kWh
 - For all consumption in excess of 400 hours times the demand, use:
 - o 5.03 cents/kWh

To set up “block within a block”, Charge:Block settings are made to separate out the first 200 kWh/kW. The “EnergyFirst200kWhPerkW” charge performs this. It uses demand to multiply the first block size by 200 and the cost for the block is simply 1 since it passes through the energy to the variable “EnergyFirst200kWhPerkW”. The remaining energy goes into the **restOfEnergy** variable as specified in the [Remaining into variable](#). After this has been evaluated we have two new variables that hold energy. Each of these variables are then separately used in Charge:Block objects to evaluate the different parts of the example tariff. By using the **Remaining into variable** along with the concept of variables, many very complex tariffs may be modelled.

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

Tariffs

☒ Include tariff analysis

Number of tariffs

1

Tariff 1

EnergyPlus Example G - Blocks within Blocks

2. On the **Tariff** tab of the Tariff dialog:

- Set the fixed monthly fee to \$35 per month using the [Input monthly service charge value](#) setting.

The Tariff tab should now look similar to the screenshot below:

Tariffs

Example H – Real Time Pricing

Some utilities offer hourly pricing that varies based on real-time market conditions which are typically announced day-ahead. Hourly energy prices are imported from a schedule, with no predefined charges. This example shows how to model real-time pricing tariffs where the utility provides hourly prices in advance.

To model this type of utility rate a schedule is used that contains the prices on an hourly basis. The [Real time pricing charge schedule](#) contains the prices and the [Customer baseline load schedule](#) setting is used to set the schedule for the customer baseline load. Not all utilities use a customer baseline load in which case this schedule does not need to be entered. The Period, Season and Month Schedules are not needed for these tariffs unless Charges are used.

The example real time pricing schedule results in the same energy cost as [Example F – Seasonal Time of Use Energy](#). Note that this is only an example and usually for real time pricing the schedule values would vary throughout the year.

To create this tariff structure, follow the steps below.

1. Create a new Tariff component:

Tariffs

☒ Include tariff analysis

Number of tariffs: 1

Tariff 1: EnergyPlus Example H - Real Time Pricing (RTP)

2. On the **Tariff** tab of the Tariff dialog:

- Set the fixed monthly fee to \$37.75 per month using the [Input monthly service charge value](#) setting.
- Check the [Use 'Real time pricing charge schedule'?](#) checkbox.
- Click on the [Real time pricing charge schedule](#) control and make a copy of the library schedule: "Real time pricing schedule". Name the copy of the schedule "RealTimePricing" and select it. The copied library schedule should already contain the right settings for this example, so for our purposes, no further changes are needed to the copy. The schedule should look like the screenshot below. Of course, for your project work, you would make the necessary edits to the copied schedule.

Example I – Selling And Net-Metering

When the building contains a generator, photovoltaics, or other sources of electrical power, there is an opportunity for the building generator to produce more power than the building uses. The excess power can either be sold to the utility or used to offset the energy purchased.

This example demonstrates two separate approaches:

- Selling to Utility:** Sell surplus electricity back to utility at a fixed credit rate. The customer is generating electricity but maintains separate accounting for purchases and sales, with different rates. Use this approach if your utility contract pays a sell-back credit at a specified rate.
- Net-Metering:** Net-metering offsets consumption using a separate tariff. A single meter runs forward for consumption and backward for generation, with net monthly billing. Use this approach if your contract allows net-metering where exported energy directly reduces consumption charges.

I.a. Selling to Utility

When the excess power is to be sold, two utility rates need to be defined, one for buying electricity from the utility and the other for times where credit is received for excess energy sent back to the grid.

In this example, tariffs and charges are set up as follows:

- Customer charge: \$2.51 per month
- Energy charge: 5.5342 cents/kWh
- Sell excess energy to utility at: 2.0 cents/kWh.

This approach uses two separate tariff objects: one for purchasing electricity and a separate one for selling excess electricity back to the utility, usually at a different (usually lower) rate. This requires defining distinct tariff components with "buyFromUtility" and "sellToUtility" buy/sell fields and meters representing purchased and sold electricity separately.

Note: A negative "Cost per value" number should be entered when credit for selling electricity to the utility is required.

To create this tariff, follow the steps below.

- The first step is to define a rate for *selling* electricity. To do this, create a new Tariff component and name it: "EnergyPlus Example Ia - Sell to Utility"
- On the **Tariff** tab of the Tariff dialog:

- Clear all cost settings
- Set the [Output meter name](#) to **4-ElectricitySurplusSold:Facility**
- Set [Buy or Sell](#) to **2-sellToUtility**

The Tariff tab should now look like the screenshot below.

Tariffs

Tariff Charge Qualify Ratchet User variables

General

Tariff name EnergyPlus Example Ia - Sell to Utility

Description Example data

Source

Category Electricity tariffs

Output meter name 4-ElectricitySurplusSold:Facility

Conversion factor choice 2-kWh

Schedules

☐ Use 'Time of use period schedule'?

☐ Use 'Season schedule'?

☐ Use 'Month schedule'?

Other Settings

Demand window length 1-QuarterHour

☐ Use 'Real time pricing charge schedule'?

☐ Use 'Customer baseline load schedule'?

☐ Use 'Group name'?

Monthly service charge

Monthly service charge or variable name 1-Charge value

Input monthly service charge value (USD) 0.0000

Minimum monthly charge

Minimum monthly charge or variable name 1-Charge value

Input minimum monthly charge value (USD) 0.0000

Buy or Sell

Buy or Sell 2-sellToUtility

3. On the **Charge** tab:

- Set the [Number of charges](#) to 1.
- Under the **Charge 1 settings** header:
 - Set [Simple or Block?](#) to **1-Simple**.
 - Set [Charge variable name](#) to **GeneratedElectricSold**
 - Set [Source variable](#) to **totalEnergy**
 - Set [Season](#) to **1-Annual**
 - Set [Category variable name](#) to **1-EnergyCharges**
 - Set [Use value or variable name](#) to **1-Value**
 - Set [Input cost per unit value](#) to -0.020

The Charge tab should now look like the screenshot below.

Tariffs	
Tariff	Charge
Charge Selection	
Number of charges	1
Charge 1 settings	
Simple or Block?	1-Simple
Charge variable name	GeneratedElectricSold
Source variable	totalEnergy
Season	1-Annual
Category variable name	1-EnergyCharges
Cost per unit value or variable name	
Use value or variable name?	1-Value
Input cost per unit value (USD)	-0.020000

Press OK to save the Tariff data and close the dialog.

The next step is to define a rate for *buying* electricity and a new Tariff component needs to be created for this.

- On the [Economics](#) model data tab, set the **Number of tariffs** to 2.
- Create a second Tariff component and name it: "EnergyPlus Example 1a - Buy from Utility".
- Open the second Tariff in the Tariff dialog and on the **Tariff** tab of the Tariff dialog, set the fixed monthly fee to \$2.51 per month using the [Input monthly service charge value](#) setting as shown below:

Tariffs

I.b. Net-Metering

In this example, a "net-metering" tariff is defined with the [Buy or Sell](#) field set to **3-netMetering**, and the [Output meter](#) set to **5-ElectricityNet:Facility**. The Tariff is set up as follows:

- Customer charge: \$30 per month
- Net metering charge: 6.5 cents/kWh

To create this tariff, follow the steps below.

1. On the [Economics](#) model data tab, set the **Number of tariffs** to 1.
2. Create a new Tariff component and name it: "EnergyPlus Example Ib - Net-Metering"

The screenshot below shows how the Economics tab should now look with the Tariff set up:

5. Open the Tariff component in the Tariff dialog and on the **Tariff** tab:

- Set the [Output meter name](#) to **5-ElectricityNet:Facility**
- Set the fixed monthly fee to \$30 per month using the [Input monthly service charge value](#) setting.
- Set [Buy or Sell](#) to **3-netMetering**

Tariffs				
Tariff	Charge	Qualify	Ratchet	User variables
General				
Tariff name	EnergyPlus Example 1b - Net-Metering			
Description	Example data			
Source				
Category	Electricity tariffs			
Output meter name	5-ElectricityNet.Facility			
Conversion factor choice	2-kWh			
Schedules				
☐ Use 'Time of use period schedule'? ☐ Use 'Season schedule'? ☐ Use 'Month schedule'?				
Other Settings				
Demand window length	1-QuarterHour			
☐ Use 'Real time pricing charge schedule'? ☐ Use 'Customer baseline load schedule'? ☐ Use 'Group name'?				
Monthly service charge				
Monthly service charge or variable name	1-Charge value			
Input monthly service charge value (USD)	30.0000			
Minimum monthly charge				
Minimum monthly charge or variable name	1-Charge value			
Input minimum monthly charge value (USD)	0.0000			
Buy or Sell				
Buy or Sell	3-netMetering			

6. On the **Charge** tab:

- Set the [Number of charges](#) to 1.
- Under the **Charge 1 settings** header:
 - o Set [Simple or Block?](#) to **1-Simple**.
 - o Set [Charge variable name](#) to **NetMeteredCharge**
 - o Set [Source variable](#) to **totalEnergy**
 - o Set [Season](#) to **1-Annual**
 - o Set [Category variable name](#) to **1-EnergyCharges**
 - o Set [Use value or variable name](#) to **1-Value**
 - o Set [Input cost per unit value](#) to 0.0650

Example J - Dual Ratchet Demand Tariff

This example shows how to model a dual ratchet demand structure where the billed demand is the greater of a rolling 12-month peak or a fixed minimum threshold. This approach is suitable for commercial tariffs that combine historical peak demand tracking with guaranteed minimum billing levels to ensure utility cost recovery.

Note: This example uses the GBP currency instead of USD. You can change [Currency](#) on the International tab of the Program options dialog.

Determination of Distribution Demand will be the highest of:

- The highest average kW measured during any 30-minute interval of the current and previous 11 billing months (rolling 12-month peak).
- A fixed minimum demand of 500 kW.

The example demonstrates two separate approaches to modelling the minimum demand:

- Ratchet Multiplier and Offset:** This approach uses a very small but non-zero multiplier in the UtilityCost:Ratchet object to simulate the minimum billing threshold.
- Block Charge based Minimum Billing:** The same minimum billing condition can be modelled directly through a UtilityCost:Charge:Block object.

J.a. Ratchet Multiplier and Offset

Use a very small but non-zero ratchet multiplier. In this case, the offset should be set to $500 \times (1 / \text{multiplier})$. For example, you can use a multiplier of 0.001 and an offset of 500,000.

To create this tariff structure, starting by ensuring you have the GBP currency set in Program options and follow the steps below.

1. Create a new Tariff component:

2. On the **Tariff** tab of the Tariff dialog:

- Set the [Demand window length](#) to **2-HalfHour** to ensure correct 30-minute average interval.

The Tariff tab should now look similar to the screenshot below:

Tariffs				
Tariff	Charge	Qualify	Ratchet	User variables
General				
Tariff name	Example Ja - Ratchet Multiplier and Offset			
Description				
Source				
Category	Electricity tariffs			
Output meter name	1-Electricity:Facility			
Conversion factor choice	2-kWh			
Schedules				
☐ Use 'Time of use period schedule'? ☐ Use 'Season schedule'? ☐ Use 'Month schedule'?				
Other Settings				
Demand window length	2-HalfHour			
☐ Use 'Real time pricing charge schedule'? ☐ Use 'Customer baseline load schedule'? ☐ Use 'Group name'?				
Monthly service charge				
Monthly service charge or variable name	1-Charge value			
Input monthly service charge value (GBP)	0.0000			
Minimum monthly charge				
Minimum monthly charge or variable name	1-Charge value			
Input minimum monthly charge value (GBP)	0.0000			
Buy or Sell				
Buy or Sell	1-buyFromUtility			

Note: The [Demand window length](#) choice may be overridden based on the value of [Simulation time step](#) so that they are consistent, i.e. demand window length should be exact multiples of the simulation time step length in minutes. For example, if the time step is 6, i.e. a 10 minutes time step, then **QuarterHour** is not used and instead **HalfHour** is used. Or if time step is 3, i.e. 20 minutes time step, then **QuarterHour** and **HalfHour** are not used and instead **FullHour** is used.

3. On the **Ratchet** tab:

- Set the Number of ratchets to 2.
- Under the **Ratchet 1** settings header:
 - Set [Ratchet variable name](#) to **BillingDemandA**
 - Set [Baseline source variable](#) to **TotalDemand**
 - Set [Adjustment source variable](#) to **TotalDemand**
 - Set [Season from](#) to **1-Annual**
 - Set [Season to](#) to **1-Annual**
 - Under the [Multiplier value or variable name](#) header, set [Use value or variable name?](#) to **1-Value**
 - Under the [Multiplier value or variable name](#) header, set [Input multiplier value](#) to 1
 - Under the [Offset value or variable name](#) header, set [Use value or variable name?](#) to **1-Value**
 - Under the [Offset value or variable name](#) header, set [Input offset value](#) to 0
- Under the **Ratchet 2** settings header:
 - Set [Ratchet variable name](#) to **BillingDemandB**
 - Set [Baseline source variable](#) to **BillingDemandA**
 - Set [Adjustment source variable](#) to **TotalDemand**
 - Set [Season from](#) to **6-Monthly**

- Set [Season to](#) to **1-Annual**
- Under the [Multiplier value or variable name](#) header, set [Use value or variable name?](#) to **1-Value**
- Under the [Multiplier value or variable name](#) header, set [Input multiplier value](#) to 0.001
- Under the [Offset value or variable name](#) header, set [Use value or variable name?](#) to **1-Value**
- Under the [Offset value or variable name](#) header, set [Input offset value](#) to 500,000

The **Ratchet** tab should now look similar to the screenshot below.

J.b. Block Charge based Minimum Billing

This same case can also be modelled in a different way. The idea is that the 500 kW ratchet essentially means the customer always pays, for example, 25 pounds every month on the demand charge. This can be implemented using a UtilityCost:Charge:Block by charging 25 GBP for the first kW, 0 GBP for the next 499 kW, and, for instance, 0.05 GBP thereafter.

1. Create a new Tariff component:

Tariffs

☒ Include tariff analysis

Number of tariffs: 1

Tariff 1: Example Jb - Block Charge based Minimum Billing

2. The **Tariff** tab should be the same as for the previous example, [J.a. Ratchet Multiplier and Offset](#)

3. On the **Charge** tab:

- Set the Number of charges to 1
- Under the **Charge 1 settings** header:
 - Set [Simple or Block?](#) to **2-Block**
 - Set [Charge variable name](#) to **DemandCost**
 - Set [Source variable](#) to **BillingDemand**
 - Set [Season](#) to **1-Annual**
 - Set [Category variable name](#) to **2-DemandCharges**
 - Leave [Remaining into variable](#) blank
 - Under the [Block size multiplier or variable name](#) header, set [Use value or variable name?](#) to **1-Value** and the [Input multiplier value](#) to 1
 - Set [Number of blocks](#) to 3
 - Set [Block size 1 value](#) to 1
 - Set [Block 1 cost per unit value](#) to 25
 - Set [Block size 2 value](#) to 499
 - Set [Block 2 cost per unit value](#) to 0
 - Set [Block size 3 variable name](#) to **remaining**
 - Set [Block 3 cost per unit value](#) to 0.05

The screenshot below shows how the charge tab should look when you have finished.

The screenshot shows the 'Tariffs' application interface with the 'Charge' tab selected. The interface is divided into several sections for configuring a charge.

Tariffs	
Tariff Charge Qualify Ratchet User variables	
Charge Selection	
Number of charges	1
Charge 1 settings	
Simple or Block?	2-Block
Charge variable name	DemandCost
Source variable	BillingDemand
Season	1-Annual
Category variable name	2-DemandCharges
Remaining into variable	
Block size multiplier value or variable name	
Use value or variable name?	1-Value
Input multiplier value	1.000
Number of blocks	3
Block size 1 value	1.00
Block 1 cost per unit value (GBP)	25.000000
Block size 2 value	499.00
Block 2 cost per unit value (GBP)	0.000000
Block size 3 value or variable name	
Use block size value or variable name?	2-Block size variable name
Block size 3 variable name	remaining
Block 3 cost per unit value (GBP)	0.050000

4. On the **Ratchet** tab:

- Set the Number of ratchets to 1.
- Under the Ratchet 1 settings header:
 - Set [Ratchet variable name](#) to **BillingDemandA**
 - Set [Baseline source variable](#) to **TotalDemand**
 - Set [Adjustment source variable](#) to **TotalDemand**
 - Set [Season from](#) to **1-Annual**
 - Set [Season to](#) to **1-Annual**
 - Under the [Multiplier value or variable name](#) header, set [Use value or variable name?](#) to **1-Value**
 - Under the [Multiplier value or variable name](#) header, set [Input multiplier value](#) to 1
 - Under the [Offset value or variable name](#) header, set [Use value or variable name?](#) to **1-Value**
 - Under the [Offset value or variable name](#) header, set [Input offset value](#) to 0

The Ratchet tab should now look similar to the screenshot below.

Further Examples

Another source of examples is the large set of tariff input objects provided with EnergyPlus in the macro data set file called "UtilityTariffObjects.imf" located in the "MacroDataSets" folder where EnergyPlus is installed. This file contains sets of objects in EnergyPlus' IDF file format that define tariffs for commercial customers from a collection of U.S. utility companies in August 2005.

Construction Costs

Component cost modelling provides an early design stage estimate of the initial construction capital costs associated with the building and services being modelled. The construction costs input to the EnergyPlus costing calculations are derived from the cost outputs from the [Carbon](#) tab of the [Cost and Carbon](#) tab. Initially, the idea of EnergyPlus construction costs is to ensure that cost estimates are consistent with the EnergyPlus model and allow using results calculated during a simulation such as equipment sizes and surface areas.

The DesignBuilder EnergyPlus cost estimating capabilities are intended for early stage estimation and do not cover all the types of analyses included in more detailed cost estimating software.

The usual reason for including component costs in an EnergyPlus simulation will be as part of a larger investment analysis such as life-cycle costing.

Note: The term "component cost" is used almost synonymously with "construction cost" in the DesignBuilder documentation. The "component cost" terminology comes from the EnergyPlus ComponentCost:LineItem, ComponentCost:Adjustments and ComponentCost:Reference data used to include construction costs in the simulation.

To understand how to include cost estimates in EnergyPlus inputs, it may help to first define some terminology and provide an overview of the process used in EnergyPlus. There are three broad steps involved in the EnergyPlus component cost calculations.

1. Construction costs are calculated by summing individual "line items" through calculations carried out on the Cost and Carbon screen.
2. Project costs are calculated by adjusting construction costs to account for other factors such as profit or design fees.
3. Finally the current simulation results are compared with equivalent results for a reference case so that marginal alterations can be calculated.

Each of above steps involves using one of the three Component cost data sets described below. These 3 steps are organized by corresponding tabs on the Construction costs dialog:

- [Line Item](#)
- [Adjustments](#)
- [Reference](#)

The results can be included in the **Construction Cost Estimate Summary** table by checking the **Component Cost Economics Summary** output option under the **Summary Annual Reports** header.

Example

The construction cost calculation example below shows the **Component Cost Economics Summary** output and how this is used as the basis for a comparison with a reference case with adjustment factors applied. The process is as follows:

1. Ensure that the Detailed HVAC model option is selected which enables the **Economics** model data tab at building level.
2. Run a [Cost calculation](#) on the Cost and Carbon tab.
3. Return to the Edit screen, navigate to the Economics tab and switch on the **Include construction costs in simulation inputs** checkbox to reveal the Construction cost component selection. The default construction cost option is called "Component cost".
4. Make a copy of the default "Component cost" Construction cost data and select it. It will be called "Copy of Component cost" by default. Working with your own component will allow you to make edits if necessary.
5. Edit the new selected "Copy of Component cost" construction cost component. On the first tab you will find the latest costs calculated on the Cost and Carbon tab, summed for each high level category.
6. Make any changes required on the [Adjustments](#) and [Reference](#) tabs and **press OK to save the costs**.
7. Go the Simulation screen and run a simulation.
8. After the simulation is complete, click on the Summary tab, click on the "Table of Contents" link and then on the "Component Cost Economics Summary" link to view the component construction costs.

	Line No.	Item Name	Quantity	Units	£ per Qty.	SubTotal £

Construction Costs - Line Item

Line item tab on [Construction cost](#) Dialog

Name

Enter the name of this Component cost component.

Description

Enter the name of this Component cost component.

Category

The category cannot be changed on the dialog.

The way line item data is entered depends on which of these 2 categories is selected:

- **DesignBuilder** - Line item data is read automatically from the current results on the [Cost and Carbon](#) tab when opening the dialog, If the [cost calculations](#) are updated then data on this dialog must also be updated by re-opening the dialog and saving it again.
- **User defined** - Up to 10 line item data items can be entered manually.

Number of line items

Enter the number of line items to be inputs up to a maximum of 10. The number is fixed at 8 for cost data from the [DesignBuilder](#) category.

Line Item N Inputs

Each line item entered creates a cost line item in the EnergyPlus input and contributes to the total building cost estimate.

When using the DesignBuilder cost estimate, all Line items are obtained by first running the [Cost and Carbon](#) calculation. The line items are obtained from the sub totals in this output:

- Structure costs
- HVAC costs
- Lighting costs
- Sub-structure costs
- Super structure costs
- Glazing costs
- Renewables costs
- Surface finish costs

For details on how these costs are calculated, refer to the [Cost and Carbon](#) calculation section.

Alternatively, you can use your own line item data (as opposed to those calculated by DesignBuilder) by selecting a Component cost component from the [User defined](#) folder. Data from this folder has all fields editable.

Line items are reported by EnergyPlus and displayed in tabular form on the [Summary](#) tab of the Simulation screen:

	Line No.	Item Name	Quantity.	Units	£ per Qty.	SubTotal £
--	1	STRUCTURE COSTS	1	Ea.	50110.62	50110.62
--	2	HVAC COSTS	1	Ea.	35793.30	35793.30
--	3	LIGHTING COSTS	1	Ea.	14317.32	14317.32
--	4	SUB-STRUCTURE COSTS	1	Ea.	28326.65	28326.65
--	5	SUPER STRUCTURE COSTS	1	Ea.	99669.80	99669.80
--	6	GLAZING COSTS	1	Ea.	10654.88	10654.88
--	7	RENEWABLES COSTS	1	Ea.	23175.25	23175.25
--	8	SURFACE FINISH COSTS	1	Ea.	25856.59	25856.59
Line Item SubTotal		--	--	--	--	287904.41

Line item type

The only option in the version is **1-General**.

Item name

This field is used to refer to a specific instance of an object.

Cost per each

This field is used to enter cost information on per-each basis. The unit is local currency.

Quantity

This field is used to directly enter the line item quantity. The units should correspond to what is used in the Per Each field.

Construction Costs - Adjustments

Adjustments tab on [Construction cost](#) Dialog

Data on the Adjustments tab can be used to allow EnergyPlus to perform various modifications to the construction costs to arrive at a more realistic estimate for total project costs than is possible through summing the construction cost line items alone. It allows the line item model to be extended so that the overall costs of the project will reflect various profit and fees.

Note: Adjustments cost data is used only in EnergyPlus simulations and is not used in DesignBuilder's [Cost calculations](#) on the [Cost and Carbon](#) tab.

Miscellaneous cost per conditioned area

This optional field can be used to enter a cost model for miscellaneous project costs that are not included in the line item modelling. Miscellaneous costs are entered in cost (local currency) per conditioned floor area. This field allows including the costs of project elements that go beyond what can be modelled using Line item objects. The value input in this field will be multiplied by the conditioned floor area and will be listed in the [Construction Cost Estimate Summary](#) table.

Regional adjustment factor

This field can be used to enter an adjustment factor to account for regional differences in construction costs. The factor will be applied to the modelled and miscellaneous construction costs to determine an amount that should be added, or subtracted, to account for local variations in construction costs. The default factor is 1.0, which means no regional adjustment. The additive adjustment is calculated by subtracting 1.0 from the value entered in this field. This field is useful for using national average data in the line item and miscellaneous construction cost models and then altering the results based on regional differences.

The total base costs calculated by applying the regional adjustment factor to be modelled and miscellaneous construction costs will be used for calculating other additional costs in terms of multiplying the fractions in the following five fields.

Design and engineering fees

This field can be used to enter a fraction of total base costs that should be added to account for design and engineering fees. Note it is not the same as a fraction of the total cost estimate.

Contractor fee

This field can be used to enter a fraction of total base costs that should be added to account for Contractor fees. Note it is not the same as a fraction of the total cost estimate.

Contingency

This field can be used to enter a fraction of total base costs that should be added for contingency. Note that is not the same as a fraction of the total cost estimate.

Permits, bonding and insurance

This field can be used to enter a fraction of total base costs that should be added to account for permitting, bonding, and insurance costs to the project. Note that is not the same as a fraction of the total cost estimate.

Commissioning fee

This field can be used to enter a fraction of total based and miscellaneous construction costs that should be added to account for commissioning services. Note that is not the same as a fraction of the total cost estimate.

Construction Costs - Reference

Reference tab on [Construction cost](#) Dialog

Data on this tab can be used to enable EnergyPlus to compare the current cost estimate with the results of a previously calculated reference building. It parallels the data on the [Adjustments](#) tab but adds a field for entering the cost line item model result for the reference building.

All the various adjustments to the project cost estimate are available here as factors that differ between the current and the reference building models to be applied. The factors entered here are applied to the reference building while the factors listed in the Adjustment object are applied to the current building model cost estimate. The results are included in the **Construction Cost Estimate Summary** table by checking the **Component Cost Economics Summary** output option.

Note: Reference cost data is used only in EnergyPlus simulations and is not used in DesignBuilder's [Cost calculations](#) on the [Cost and Carbon](#) tab.

Reference line item costs

This field is used to enter a cost representing the total for the reference building to be compared to the line item cost model for the current building model. A typical source of data for this would be the "Line Item Subtotal" from a previous simulation.

Reference miscellaneous cost per conditioned area

This field can be used to enter a cost model for miscellaneous project costs that are not included in the line item modelling. Miscellaneous costs are entered in cost (local currency) per conditioned floor area. This field allows including the costs of project elements that go beyond what can be modelled using Line item objects. The value input in this field will be multiplied by the conditioned floor area and listed in the **Construction Cost Estimate Summary** table.

Reference regional adjustment factor

This field can be used to enter an adjustment factor to account for regional differences in construction costs. The factor will be applied to the modelled and miscellaneous construction costs to determine an amount that should be added, or subtracted, to account for local variations in construction costs. The default factor is 1.0, which means no regional adjustment. The additive adjustment is calculated by subtracting 1.0 from the value entered in this field (e.g. 1.05 means a 5% increase).

This field is useful for using national average data in the line item and miscellaneous construction cost models and then altering the results based on regional differences.

The total base costs calculated by applying regional adjustment factor to modelled and miscellaneous construction costs will be used for calculating other additional costs in terms of multiplying the fractions in the following five fields.

Reference design and engineering fees

This field can be used to enter a fraction of total base costs that should be added to account for design and engineering fees. Note that it is not the same as a fraction of the total cost estimate.

Reference contractor fee

This field can be used to enter a fraction of total base costs that should be added to account for Contractor fees. Note that it is not the same as a fraction of the total cost estimate.

Reference contingency

This field can be used to enter a fraction of total base costs that should be added for contingency. Note that it is not the same as a fraction of the total cost estimate.

Reference permits, bonding and insurance

This field can be used to enter a fraction of total base costs that should be added to account for permitting, bonding, and insurance costs to the project. Note that it is not the same as a fraction of the total cost estimate.

Reference commissioning fee

This field can be used to enter a fraction of total base costs that should be added to account for commissioning services. Note that it is not the same as a fraction of the total cost estimate.

Life Cycle Cost

Life-cycle costing (LCC) is used with building energy simulation in order to justify energy efficiency upgrades. Many alternative building technologies that result in energy savings cost more initially, or may cost more to maintain, than traditional solutions. In order to justify selecting these energy savings technologies, it is essential to combine both initial and future costs in the decision process. Using life-cycle costs provides a framework to combine initial costs and future costs into a single combined measure, called the “present value.” Present value is a metric that combines all costs and reduces (or discounts) those costs that occur in the future. Discounting future costs is based on the principal of the time value of money.

The calculations are based on discounting the future values according to normal life-cycle costing techniques as described in NIST Handbook 135 [Life-Cycle Costing Manual for the Federal Energy Management Program](#).

The following is a list of life-cycle costing related data that provide a way to describe the parameters and costs associated with the life-cycle of a building or building system. These objects are organized by tabs on the Life Cycle Cost dialog:

- [Parameters](#)
- [Recurring costs](#)
- [Non-recurring costs](#)
- [Use price escalation](#)
- [Use adjustment](#)

The [utility costs](#) and [first costs](#) are used along with other current and future costs input using the Recurring costs and Non-recurring cost data and these are combined into the present value life-cycle cost metric. The Parameters object establishes the set of assumptions for the analysis along with Use price escalation (often from databases) and Use adjustment objects.

Note 1: It is important to understand that the comparison of different simulation results and their present values is not performed by EnergyPlus. Instead, EnergyPlus provides the present value calculations for a specific simulation combining the energy costs, first costs, and future costs and you need to make the comparison between the results of multiple simulations when needed.

Note 2: Life-Cycle Costing (LCC) should not be confused with [Life Cycle Analysis](#) (LCA). With LCC the result is an economic evaluation of current and future expenditures in order to make a decision on alternative investments. In LCA, the environmental impact such as equivalent CO2 production involved in the materials, delivery, manufacturing, and construction are combined with environmental impacts of the building in operation and the eventual removal of the building and is used to understand the overall environmental impact or embodied energy.

Tip: You can carry out powerful analyses to simultaneously optimise whole life cycle cost and whole life cycle environmental impact performance using DesignBuilder's optimisation tools. Choose the [LCC](#) and [LCA](#) KPIs for this sort of analysis.

Output

The results of using the LCC analysis are included automatically in the Summary report under “Life Cycle Cost Report.” This report shows the costs and the timing of costs, often called “cash flows,” along with the present value in several different tables. The tabular results show the present value of all current and future costs.

Life Cycle Cost - Parameters Tab

Parameters tab on [Life Cycle Cost Dialog](#)

Provides inputs related to the overall life-cycle cost analysis. It establishes many of the assumptions used in computing the present value. It is important that when comparing the results of multiple simulations that the fields in the Parameters objects are the same for all the simulations. To help check this is the case, the first table in the Life-Cycle Cost Report shows the inputs to this object.

Name

An identifying name this LCC analysis.

Discount Settings

Discounting convention

The field specifies if the discounting of future costs should be computed as occurring at the end, the middle or the beginning of each year. The most common discounting convention uses the end of each year, therefore without a specific reason, the end of year should be used. The year being used starts with the base year and month (see below) and repeats every full year.

All costs assumed to occur during that duration are accumulated and shown as an expense either at the beginning, middle or end of the year. The options are:

- **1-BeginningOfYear**
- **2-MidYear**
- **3-EndOfYear**

Note: Specifically, some military projects may require using the middle of each year.

Inflation approach

This field is used to determine if the analysis should use constant dollars or current dollars which is related to how inflation is treated. The two options are:

- **1-ConstantDollar** (Default option)
- **2-CurrentDollar**

If **1-ConstantDollar** is selected, then the Real discount rate input (see below) is used and it excludes the rate of inflation. If **2-CurrentDollar** is selected, then the Nominal discount rate (see below) input is used and it includes the rate of inflation. For most analyses, using the **1-ConstantDollar** option will be easier since the effect of inflation may be ignored.

Reference: From NIST Handbook 135: "The constant dollar approach has the advantage of avoiding the need to project future rates of inflation or deflation. The price of a good or service stated in constant dollars is not affected by the rate of general inflation. For example, if the price of a piece of equipment is \$1,000 today and \$1,050 at the end of a year in which prices in general have risen at an annual rate of 5 percent, the price stated in constant dollars is still \$1,000; no inflation adjustment is necessary. In contrast, if cash flows are stated in current dollars, future amounts include general inflation, and an adjustment is necessary to convert the current dollar estimate to its constant-dollar equivalent. This adjustment is important because constant- and current-dollar amounts must not be combined in an LCCA."

Real discount rate

Enter the real discount rate as a decimal, e.g. for a 3% rate, enter the value 0.03. This input is used when the [Inflation approach](#) is **1-ConstantDollar**. The real discount rate reflects the interest rates needed to make current and future expenditures have comparable equivalent values when general inflation is ignored. When the [Inflation approach](#) is set to **2-CurrentDollar** this input is ignored.

Nominal discount rate

Enter the nominal discount rate as a decimal, e.g. for a 5% rate, enter the value 0.05. This input is used when the [Inflation approach](#) is **2-CurrentDollar**. The nominal discount rate reflects the interest rates needed to make current and future expenditures have comparable equivalent values when general inflation is included. When [Inflation approach](#) is set to **1-ConstantDollar** this input is ignored.

Inflation rate

Enter the rate of inflation for general goods and services as a decimal, e.g. for a 2% rate, enter the value 0.02. When [Inflation approach](#) is set to **1-ConstantDollar** this input is ignored.

Example: Below is an example from the NIST Handbook 135 1995 edition.

The following example shows that both approaches result in the same present value and thus support the same decision.

Example: Suppose you want to know the present value of an AC compressor that you expect to replace in 15 years. If it were replaced today, the price would be \$5,000. Due to advanced manufacturing processes, you expect that the price of compressors will increase at a rate of 2 percent lower than general price inflation. You estimate the rate of general price inflation to be 5 percent per year. You know that your real discount rate is 3 percent. To sum

$I = 0.05$	$t = 15 \text{ years}$
$d = 0.03$	$D = (1 + 0.03)(1 + 0.05) - 1 = 0.0815$
$e = -0.02$	$E = (1 - 0.02)(1 + 0.05) - 1 = 0.029$

real discount rate, d

nominal discount rate, D

**Constant dollars and
real discount rate**

**Current dollars and
nominal discount rate**

$$\begin{aligned}
 PV &= F_t \times \left[\frac{1 + e}{1 + d} \right]^t \\
 &= 5000 \times \left[\frac{1 - 0.02}{1 + 0.03} \right]^{15} \\
 &= 5000 \times 0.4741 \\
 &= \$2,370.30
 \end{aligned}$$

$$\begin{aligned}
 PV &= F_t \times \left[\frac{1 + E}{1 + D} \right]^t \\
 &= 5000 \times \left[\frac{1 + 0.029}{1 + 0.0815} \right]^{15} \\
 &= 5000 \times 0.4741 \\
 &= \$2,370.30
 \end{aligned}$$

Dates For Study

Base date month

Enter the month that is the beginning of study period, also known as the beginning of the base period. The options are:

- **1-January** (default)

- 2-February
- 3-March
- 4-April
- 5-May
- 6-June
- 7-July
- 8-August
- 9-September
- 10-October
- 11-November
- 12-December

Reference: According to NIST 135 “the base date is the point in time to which all project related costs are discounted in an LCCA [life cycle cost analysis]. The base date is usually the first day of the study period for the project, which in turn is usually the date that the LCCA is performed. In a constant dollar analysis, the base date usually defines the time reference for the constant dollars (e.g. 1995 constant dollars). It is essential that you use the same base date and constant-dollar year for all of the project alternatives to be compared. If you set the base date to the date that the LCCA is performed, then the constant dollar basis for the analysis will be the current date, and you can use actual costs as of that date without adjusting for general inflation.”

Base date year

Enter the four digit year that is the beginning of study period, such as a year expressed in four digits like “2011”. The study period is also known as the base period. See more details in the previous field.

Service date month

Enter the month that is the beginning of building occupancy. Energy costs computed by EnergyPlus are assumed to occur during the year following the service date. The service date must not be earlier than the Base date. The options are:

- 1-January (default)
- 2-February
- 3-March
- 4-April
- 5-May
- 6-June
- 7-July
- 8-August
- 9-September
- 10-October
- 11-November
- 12-December

Service date year

Enter the four digit year that is the beginning of occupancy, such as two years after the previously entered year expressed in four digits so example is like “2013”.

Reference: According to NIST Handbook 135: “The service date is the date on which the project is expected to be implemented; operating and maintenance costs (including energy- and water-related costs) are generally incurred after this date, not before.”

Other Settings

Length of study period in years

Enter the number of years of the study period. It is the number of years that the study continues based on the start at the base date.

The default value is 25 years, and only integers are allowed that indicate whole years.

Reference: According to NIST Handbook 135, “the study period for an LCCA is the time over which the costs and benefits related to a capital investment decision are of interest to the decision maker. Thus, the study period begins with the base date and includes both the planning/construction period (if any) and the relevant service period for the project. The service period begins with the service date and extends to the end of the study period.”

Tax rate

Enter the overall marginal tax rate for the project costs. This does not include energy or water taxes. The single tax rate entered here is not intended to be a replacement of the complex calculations necessary to compute personal or corporate taxes; instead it is an approximate that may be used for a simple analysis assuming a constant tax rate is applied on all costs. The tax rate entered should be based on the marginal tax rate for the entity and not the average tax rate. Enter the tax rate results in present value calculations after taxes. Most analyses do not factor in the impact of taxes and assume that all options under consideration have roughly the same tax impact. Due to this, many times the tax rate can be left to default to zero and the present value results before taxes are used to make decisions. The value should be entered as a decimal value, e.g. for 15% enter 0.15. For an analysis that does not include tax impacts, enter 0.0. The default is 0.

Depreciation method

For an analysis that includes income tax impacts, this entry describes how capital costs are depreciated. Only one depreciation method may be used for an analysis and is applied to all capital expenditures. Only analyses that include tax impacts need to select a depreciation method. The options are:

- **1-ModifiedAcceleratedCostRecoverySystem-3year**
- **2-ModifiedAcceleratedCostRecoverySystem-5year**
- **3-ModifiedAcceleratedCostRecoverySystem-7year**
- **4-ModifiedAcceleratedCostRecoverySystem-10year**
- **5-ModifiedAcceleratedCostRecoverySystem-15year**
- **6-ModifiedAcceleratedCostRecoverySystem-20year**
- **7-StraightLine-27year**
- **8-StraightLine-31year**
- **9-StraightLine-39year**
- **10-StraightLine-40year**
- **11-None** (default)

Depreciation allowances reduce the actual/nominal tax dollars paid by the owner. Thus, analyses using depreciation should be conducted in nominal dollars. For an analysis that does not include tax effects, **11-None** should be selected.

Note: For more details about depreciation methods and which one to choose, refer to IRS Publication 946 – How to Depreciate Property. It states that "Depreciation is an annual income tax deduction that allows you to recover the cost or other basis of certain property over the time you use the property. It is an allowance for Fair market value the wear and tear, deterioration, or obsolescence of the Intangible property." Details on which depreciation method to choose depends on the property being depreciated, IRS Publication 946 and your accountant will be the best sources of information in determining which depreciation method to choose.

Life Cycle Cost - Recurring Costs Tab

Recurring costs tab on [Life Cycle Cost Dialog](#)

Recurring costs are costs that repeat over time on a regular schedule during the study period. If costs associated with equipment do repeat but not on a regular schedule, use the [Non-recurring costs](#) tab instead.

Number of recurring costs

The number of recurring costs applied in this life-cycle cost can be selected from the dropdown list. For each recurring cost the following data must be entered.

Recurring Cost N Settings

Name

The identifier used for this recurring cost. The name is used in identifying the cash flow equivalent in the output results in the Life-Cycle Cost Report.

Category

Enter the category of the recurring costs. Choose the closest category. The options include:

- **1-EnergyCosts**
- **2-WaterCosts**
- **3-Maintenance**
- **4-Repair**
- **5-Operation**
- **6-Replacement**
- **7-MinorOverhaul**
- **8-MajorOverhaul**
- **9-OtherOperational**

The default value is **3-Maintenance**.

Note: For recommendations on estimating other operational costs, see NIST 135 Section 4.6.3.

Cost

Enter the cost (local currency) for the recurring costs. Enter the cost for each time it occurs. For example, if the annual maintenance cost is \$500, enter 500 here.

Start of costs

Enter when the costs start. The First year of cost is based on the number of years past the **Start of costs**. For most maintenance costs, the **Start of costs** should be **1-ServicePeriod**. The options are:

- **1-ServicePeriod**
- **2-BasePeriod**

The default value is **1-ServicePeriod**.

Years from start

This field and **Months from start** (below) together represent the time from either the start of the Service period, on the service month and year, or start of the base period, on the base month and year (depending on selection from the **Start of costs** field) that the costs start to occur. Normally, for most maintenance costs that

begin in the first year that the equipment is in service the **Start of costs** is the service period and the **Years from start** will be 0. Only integers should be entered representing whole years. The default value is 0.

Months from start

This field and **Years from start** (above) together represent the time from either the start of the Service period, on the service month and year, or start of the base period, on the base month and year (depending on the **Start of costs** field) that the costs start to occur. Normally, for most maintenance costs the **Start of costs** is the Service period and the **Months from start** will be 0. Only integers should be entered representing whole months. The **Years from start** (times 12) and **Months from start** are added together. The default value is 0.

Repeat period years

This field and **Repeat period months** (below) indicate how much time elapses between re-occurrences of the cost. For costs that occur every year, such as annual maintenance costs, the **Repeat period years** should be 1 and **Repeat period months** should be 0. Only integers should be entered representing whole years. The default value is 1.

Repeat period months

This field and **Repeat period years** (above) indicate how much time elapses between re occurrences of the cost. For costs that occur every year the **Repeat period years** should be 1 and **Repeat period months** should be 0. For, costs that occur every eighteen months, the **Repeat period years** should be 1 and the **Repeat period months** should be 6. Only integers should be entered representing whole years. The **Repeat period years** (times 12) and **Repeat period months** are added together. The default value is 0.

Annual escalation rate

Enter the annual escalation rate as a decimal. For a 1% rate, enter the value 0.01. This input is used only when the [Inflation approach](#) is **2-CurrentDollar**. The default value is 0.

Life Cycle Cost - Non-Recurring Costs Tab

Non-Recurring costs tab on [Life Cycle Cost](#) Dialog

A non-recurring cost happens only once during the study period. For costs that occur more than once during the study period on a regular schedule, use the [Recurring costs](#) tab.

Number of non-recurring costs

The number of non-recurring costs applied in this life-cycle cost can be selected from this dropdown list. For each non-recurring cost the following data must be entered.

Non-Recurring Cost N Settings

Name

The identifier used for the object. The name is used in identifying the cash flow equivalent in the output results in the Life-Cycle Cost Report.

Category

Enter the category of the non-recurring costs. Choose the closest category. The options include:

- **1-Construction**
- **2-Salvage**
- **3-OtherCapital**

The default is **1-Construction**.

Reference: For recommendations on estimating capital and salvage (residual) costs, see NIST 135 Section 4.5.

Cost

Enter the non-recurring cost value. For construction and other capital costs the value entered is typically a positive value. For salvage costs, the value entered is typically a negative value which represents the money paid to the investor for the equipment at the end of the study period.

Start of costs

Enter when the costs start. The first year of cost is based on the number of years past the **Start of costs**. For most non-recurring costs the **Start of costs** should be base period which begins at the base month and year. The options are:

- **1-ServicePeriod**
- **2-BasePeriod**

The default value is **2-BasePeriod**.

Years from start

This field and **Months from start** (below) together represent the time from either the start of the service period, on the service month and year, or start of the base period, on the base month and year (depending on the **Start of cost** field) that the costs start to occur. Normally, for most capital costs the **Start of costs** is the base period and the **Years from Start** will be 0. These would be first costs for the building equipment or system. Salvage costs are usually shown as happening in the last year of the analysis. Only integers should be entered representing whole years. The default value is 0.

Months from start

This field and **Years From start** (above) together represent the time from either the start of the service period, on the service month and year, or start of the base period, on the base month and year (depending on the **Start of cost** field) that the costs start to occur. Normally, for most capital costs the **Start of costs** is the base period and the **Months from start** will be 0. Only integers should be entered representing whole months. The **Years From start** (times 12) and **Months from start** are added together. The default value is 0.

Life Cycle Cost - Use Price Escalation Tab

Use price escalation tab on [Life Cycle Cost Dialog](#)

The Use price escalation data will commonly be part of a dataset on life cycle costs.

Reference: The values for this object may be found in the annual supplement to NIST Handbook 135 in Tables Ca-1 to Ca-5. A dataset file comes with EnergyPlus in the DataSet directory and includes the LCCUsePriceEscalationDataSetXXXX.idf file which includes the value for the supplement to NIST 135 from the year indicated. The object provides inputs for the escalations of energy and water costs assuming that they change differently than inflation. According to the NIST 135 supplement the values are “present projected fuel price indices for the four Census regions and for the United States. These indices, when multiplied by annual energy costs computed at base-date prices provide estimates of future-year costs in constant base-date dollars. Constant-dollar cost estimates are needed when discounting is performed with a real discount rate (i.e., a rate that does not include general price inflation).”

The **LCCUsePriceEscalationDataSetXXXX.idf** is periodically updated by the EnergyPlus development team using data available from NIST along with a spreadsheet to convert that data into an IDF dataset file. The NIST 135 annual supplement is available from NIST or through US DOE FEMP program.

<https://nvlpubs.nist.gov/nistpubs/ir/2019/NIST.IR.85-3273-34.pdf>

If requested, NIST personnel will provide a file called ENCOSTxx.TXT which contains the data used to create Table Ca-1 to Table Ca-5 in the supplement. To convert the data in the ENCOSTxx.TXT file to an IDF file, open the ENCOSTxx.TXT file in a text editor and copy the entire contents into the first tab called “Step 1” of the conversion spreadsheet. The conversion spreadsheet file named

ConvertENCOSTtoEnergyPlusLifeCycleCost.xls is available upon request from the EnergyPlus development team. The “Step 2” tab separates the data into columns. The “Step 3” tab computes ratios that are the same as Table Ca-1 to Table C1-6 in the supplement. Checking these values against what appears in the printed supplement is recommended. The “Step 4” and “Step 5” tabs rearrange the data and the “Step 6” tab shows the data in a format that can be easily copied and pasted into a new idf dataset file. The final step requires using your text editor to replace the fuel names with those used by EnergyPlus. The replacement names are listed on the “FuelNameConversion” tab.

Number of escalations used

The number of price escalations applied in this life-cycle cost can be selected from this dropdown list. The following fields can be repeated up to the number selected in this field.

Use Price Escalation N Settings

Name

The identifier used for this escalation. The name usually identifies the location (such as the state, region, country or census area) that the escalations apply to. In addition the name should identify the building class such as residential, commercial, or industrial and the use type such as electricity, natural gas, or water.

Resource

Select the resource from:

- **1-Electricity**
- **2-FuelOil1**
- **3-NaturalGas**
- **4-PropaneGas**
- **5-FuelOil2**
- **6-Coal**
- **7-Steam**
- **8-Gasoline**
- **9-Diesel**
- **10-Water**

Escalation start year

This field and the **Escalation start month** define the time that corresponds to “Year 1 Escalation” such as a year expressed in four digits like “2013”, when the escalation rates are applied. This field and the **Escalation start month** define the time that escalation begins.

Escalation start month

This field and the **Escalation start year** define the time that corresponds to “Year 1 Escalation” such as a year expressed in four digits such as “2013”, when the escalation rates are applied. This field and the **Escalation start year** define the time that escalation begins. The options are:

- **1-January** (default)
- **2-February**
- **3-March**
- **4-April**
- **5-May**
- **6-June**

- 7-July
- 8-August
- 9-September
- 10-October
- 11-November
- 12-December

Number of years of escalation

This number can be selected by the dropdown list. Often 25 to 50 years of projected values are required.

Escalation Data

Year 1 escalation

The escalation in price of the energy or water use for the first year expressed as a decimal.

Year n escalation

The escalation in price of the energy or water use for the n-th year expressed as a decimal. As mentioned above, normally 25 to 50 years data is used.

Note: If the number of years of escalation is less than the number of years in the analysis period, the remaining years will assume no escalation, therefore normal inflation will be the only affect for these years.

Life Cycle Cost - Use Adjustment Tab

Used by advanced users to adjust the energy or water use costs for future years. This should not be used for compensating for inflation but should only be used to increase the costs of energy or water based on assumed changes to the actual use of water or energy, such as due to changes in the future function of the building or the impact of future adjacent buildings on energy use. This object is not commonly used and should be used with caution. The adjustments begin at the start of the service period.

Number of adjustments used

The number of adjustments applied in this life-cycle cost can be selected from this dropdown list. The following fields can be repeated up to the number selected in this field.

Adjustment N Settings

Name

The identifier used for this use adjustment data.

Resource

Select the resource from:

- 1-Electricity
- 2-FuelOil1
- 3-NaturalGas
- 4-PropaneGas
- 5-FuelOil2
- 6-Coal
- 7-Steam
- 8-Gasoline

- [9-Diesel](#)
- [10-Water](#)

Number of years of adjustment

This number can be selected by the dropdown list. Often 25 to 50 years of values are required.

Adjustment Data

Year 1 multiplier

The multiplier to be applied to the end use cost for the first year in the service period. The total utility costs for the selected end use is multiplied by this value. For no change enter 1.0.

Year n multiplier

The multiplier to be applied to the end use cost for each following year. The total utility costs for the selected end use is multiplied by this value. For no change enter 1.0.

Note: If the number of years of Use price escalation is less than the number of years in the analysis period, the remaining years will assume no escalation, therefore normal inflation will be the only affect for these years.

Miscellaneous

Miscellaneous tab in model data

You can control the output data that is generated in the design calculations and simulations as well as various other miscellaneous calculation settings by making selections on the **Miscellaneous** model data tab.

- "Outputs - General" on page 638
- [Heating Design Output Options](#)
- [Cooling Design Output Options](#)
- [Simulation Output Options](#)
- "Daylighting Outputs" on page 642

Outputs - General

[Miscellaneous](#) model data tab

Name in last EnergyPlus calculation

This is the IDF name of the current building, zone, surface or opening. The IDF name is set when the model inputs for an EnergyPlus simulation are being generated.

For surfaces and openings it is possible for more than one EnergyPlus objects to be generated per corresponding DesignBuilder object, and in this case multiple IDF names are separated by commas.

Tag

You can enter your own tag text to define the current object for use in [EMS optional arguments](#) and [target selection tools](#).

Output Options - Heating Design

[Heating Design](#) tab on [Model Options](#) dialog, General tab on [Heating Design Calculation Options](#) dialog and [Miscellaneous](#) model data tab

Heating design output options apply to the whole building and are only visible at building level when accessed from the [Outputs](#) model data tab.

Include unoccupied zones in block and building totals and averages

By default data for unoccupied zones is *excluded* from block and building totals and averages. Check this option to include data for unoccupied zones.

A zone is defined as unoccupied if it has:

- No occupancy and,
- No cooling and,
- No heating and,
- No mechanical ventilation

Note: if you uncheck this option and all zones in the model are unoccupied then you will get a 'Zero floor area error' message

Store surface output

Causes the following output to be stored for all walls, floors, roofs, ceilings, partitions etc:

- Inside Surface Temperature
- Outside Surface Temperature
- Glazing Heat Loss
- Internal Convective Heat Transfer Coefficient
- External Convective Heat Transfer Coefficient

Store opening output

Only visible when the [Store surface output](#) option is selected, this option causes the following data to be stored for windows vents, doors, holes, sub-surfaces:

- Inside Surface Temperature
- Outside Surface Temperature
- Glazing Heat Loss
- Internal Convective Heat Transfer Coefficient
- External Convective Heat Transfer Coefficient

Warning: Use the surface and opening output options with caution on large models as, when selected, they will cause large amounts of data to be stored.

Output Options - Cooling Design

[Cooling Design](#) tab on [Model Options](#) dialog, General tab on [Cooling Design Calculation Options](#) dialog and [Miscellaneous](#) model data tab

Cooling design output options apply to the whole building and are only visible at building level when accessed from the [Outputs](#) model data tab.

Include unoccupied zones in block and building averages and totals

By default, data for unoccupied zones is *excluded* from block and building totals and averages. Check this option to include data for unoccupied zones.

A zone is defined as unoccupied if it has:

- No occupancy and,
- No cooling and,
- No heating and,
- No mechanical ventilation

Note: if you uncheck this option and all zones in the model are unoccupied then you will get a 'Zero floor area error' message

Store surface output

Causes the following output to be stored for all walls, floors, roofs, ceilings, partitions etc:

- Inside Surface Temperature
- Outside Surface Temperature
- Surface Heat Gain
- Solar Incident
- External Sunlit Fraction
- Internal Convective Heat Transfer Coefficient
- External Convective Heat Transfer Coefficient

Store opening output

Only visible when the [Store surface output](#) option is selected, this option causes the following data to be stored for windows vents, doors, holes, sub-surfaces:

- Inside Surface Temperature
- Outside Surface Temperature
- Glazing Heat Gain
- Solar Incident
- Solar Transmitted
- External Sunlit Fraction
- Internal Convective Heat Transfer Coefficient
- External Convective Heat Transfer Coefficient

Warning: Use the surface and opening output options with caution on large models as, when selected, they will cause large amounts of data to be stored.

Simulation Output Options

[Miscellaneous](#) model data tab

General

Output options

Simulation output options can be accessed at building, block, zone, surface and opening levels giving you control of the elements in the model for which output data will be generated.

The way that output options are accessed on the Miscellaneous model data tab depends on the setting of the [Allow custom outputs](#) option which is always available at building level here on the Miscellaneous tab and also on the Simulation tab of the Model options dialog and on the Output tab of the Simulation Calculation Options dialog. When **Allow custom outputs** is unselected (the default setting) all simulation output options can be accessed from the building level only of the Miscellaneous model data tab. There is no flexibility to select different options for different blocks, zone, surfaces and opening. However when **Allow custom outputs** is selected you can select most of the outputs on a zone-by-zone, surface-by-surface and opening-by-opening basis.

Note: All of the output options listed below are explained in more detail on the main [Output options](#) page.

Firstly these output options are always only available at building level, since they apply to all results:

- [Building and block output of zone data](#)
- [Include unoccupied zones in block and building total and averages](#)
- [Allow custom outputs](#)

These outputs are available at building level only when **Allow custom outputs** is unselected, or at building, block and zone levels when it is selected:

Energy:

- [Surface heat transfer](#)
- [Internal gains including solar](#)
- [Energy, HVAC etc](#)
- [Latent loads](#)

Comfort and Environmental:

- [Environmental](#)
- [Fresh air supply](#)
- [Simple ASHRAE Standard 55](#)
- [Adaptive ASHRAE Standard 55](#)
- [CIBSE TM52](#)
- [CIBSE TM59](#)

[Detailed Daylight outputs](#)

[Summary Annual reports](#)

[Summary Monthly reports](#)

[Miscellaneous outputs](#)

Store surface output

When the [Allow custom outputs](#) option is *unselected*:

The Store surface output and Store opening output options are available at building level only. You can therefore choose whether or not to generate *all* data for *all* surfaces, and likewise for *all* openings. It is not possible to be selective in this case, i.e. it is not possible to select outputs surface-by-surface or opening-by-opening.

Otherwise when **Allow custom outputs** is *selected*:

The surface and opening outputs option options are available at block, zone, surface and opening levels. To access the output options for a particular surface or opening, you should first navigate to that

surface or opening and switch on the **Store surface output** option. This causes results for that surface or opening to be generated and stored but it does not yet select any results for display.

While these settings are used by the program at surface and opening levels, the normal rules of inheritance apply, so you can, for example, navigate to a zone and select the default output options for all surfaces and openings in that zone.

To request surface or opening results select from these options:

- **Store opening/sub-surface output** - *at surface level and above in the model hierarchy, this is a default value for openings and sub-surfaces.* It must be selected for a particular opening if any data for that opening or sub-surface is to be generated.
- **Inside Surface Temperature** - for surfaces and openings.
- **Outside Surface Temperature** - for surfaces and openings.
- **Surface Heat Gain** - for surfaces.
- **Glazing Heat Gain** - for openings.
- **Solar Incident** - for surfaces and openings.
- **Solar Transmitted** - for window openings.
- **External Sunlit Fraction** - for surfaces and openings.
- **Internal Convective Heat Transfer Coefficient** - for surfaces and openings.
- **External Convective Heat Transfer Coefficient** - for surfaces and openings.
- **Airflow** - infiltration and ventilation data is available at both surface and opening level when using the [Calculated natural ventilation](#) model option.

See: "Surface and Opening Levels" on page 1629 for information on the data generated when these surface and opening level options are selected.

Warning: Use these surface and opening output options with caution on large models as, when selected, they will cause large amounts of data to be generated and stored. You should select only the data you need for the building elements of interest.

Daylighting Outputs

[Miscellaneous](#) model data tab

Working plane height

Enter the working plane height above the top of the floor (in m or ft). This can be entered at building, block or zone level and is used by DesignBuilder at zone level. It allows you to enter different working plane heights for different zones.

Note: The same attribute can be accessed on the [Daylighting calculation options](#) dialog but for building level only .

CFD

CFD tab in model data

This tab allows you set various types of boundary condition for [CFD calculations](#).

If you have previously loaded simulation results as boundary conditions using the [CFD Boundary Conditions Edit](#) dialog then this data will be displayed at surface and opening levels.

CFD Boundary Defaults

The attributes that can be set on this tab are shown with the boundary condition type to which they apply. Note that all attributes are displayed at zone level and above in the hierarchy because these act as defaults, but at surface and opening level only the data applicable to the current object is displayed.

Note: Data specified on this tab does not affect EnergyPlus simulations.

Inside surface temperature (internal surfaces)

Applies to: *All Internal surfaces and all internal openings*

This setting provides a default inside surface temperature (in °C or °F) for internal surfaces (partitions, internal floors and ceilings) as well as all internal openings. It can be set for all levels in the model hierarchy from building level down.

This value is also used for virtual partitions to represent the average temperature of the surfaces in the adjacent room.

Important Note: Zero thickness internal partitions and floors/ceilings separating two zones in a block or building level CFD simulation are ignored, and in this case the domain will be seen as a single contiguous space. This boundary condition setting therefore has no effect on the simulation in this case.

Inside surface temperature (external surfaces)

Applies to: *All external surfaces and external doors and sub-surfaces*

This setting provides a default inside surface temperature (in °C or °F) for all external opaque surfaces and openings, including walls, roofs, external floors etc as well as external doors and sub-surfaces. It can be set for all levels in the model hierarchy from building level down.

It does not include external windows though, which are included in the item below.

Inside surface window temperature (external windows)

Applies to: *External windows*

This setting defines the inside surface temperature for external windows (in °C or °F). It can be set for all levels in the model hierarchy from building level down.

Incoming air temperature

Applies to: *Windows, Vents, Doors and Holes*

Temperature of air entering the space through windows, vents, doors and holes (in °C or °F).

Incoming air temperature

Applies to: *Supply diffusers*

Temperature of air entering the space through [Supply diffusers](#) (in °C or °F).

Flow in

Applies to *Windows, Vents, Doors and Holes*

Defines the flow rate through the opening into the zone (in l/s or ft3/min).

Flow out

Applies to *Windows, Vents, Doors and Holes*

Defines the flow rate through the opening out of the zone (in l/s or ft³/min).

Component Blocks, Assemblies and CFD Boundary Condition Patches

Data on this tab is also used for entering boundary conditions for component blocks, assemblies and for boundary condition patches drawn onto zone or component block surfaces. For details see:

- [Component Blocks and Assemblies as CFD Boundaries](#)
- [Boundary Conditions for Internal CFD Analyses](#)

See also:

- [CFD Boundary Conditions Editor](#)
- [Preparing Simulations to Generate CFD Boundary Conditions](#)

CFD Boundary Conditions Editor

The CFD Boundary Conditions Editor allows you to view and edit all of the boundary conditions in the selected domain in one place. In particular you can:

- Check and set the airflow rate through each supply and extract boundary condition and also through each window, vent, door and hole in the selected domain.
- Check that total flow in balances with total flow out (a key requirement for the CFD calculations). If flows do not balance there are options to automatically apply a correction flow to one of the existing openings to ensure balance.
- Check and set the temperatures of each boundary condition where temperature is defined (surfaces, supply flow, windows, temperature boundary conditions).
- Import surface and opening boundary conditions for a specific time/date from a previous EnergyPlus simulation.

CFD Analysis Domain

You can select the CFD Analysis domain from previously defined CFD Analyses - this defines the extent of the model that is displayed and checked for flow balance. If you have more than one analysis then you must make sure to select the correct one here before starting. Alternatively you can select the whole building or the

current block or zone. This selection does not limit the EnergyPlus simulation data that is imported, it only defines the boundary condition data that is displayed on the dialog and the domain for airflow balance checks.

Group

The Group options allows you to group boundary condition data by one of:

- **1-None** - each boundary condition is displayed in a simple list without any grouping.
- **2-Boundary types** - boundary conditions are displayed groups according to type (extract, supply, temperature, window etc). See screenshot above.
- **3-Zones and surfaces** - the boundary conditions are grouped by zone and then by surface.

Under some circumstances the display can be erratic when using the **2-Boundary type** grouping and in this case you may find it better to use one of the other grouping options.

You can edit the **flow in** and **flow out** airflow rates and temperatures as appropriate on the dialog and the changes are only saved to the model when you press the OK button. No changes are made if you press Cancel.

Edit Boundary Conditions

Airflow

The Zone, Surface, Boundary and Boundary Type columns indicate the local of the boundary condition and it's type. You can edit the flow rates in the Flow In and Flow Out columns for windows, vents, doors and holes and the Flow In for supply diffusers and Flow Out for extracts.

If flows do not already balance this will be indicated in red on the Info panel to the right and you can select one of the openings in the dialog and click on the **Correct balance using selected opening** link. A flow is added or subtracted as appropriate to get flows to balance.

Temperature

You can edit the temperature for all temperature-related boundary conditions. There are 2 temperature columns, one for surface temperatures and the other for air temperature. The air temperature column is only relevant for openings and supply diffusers and is the temperature of the air entering the space. Openings such as windows, vents and doors can have different surface and air temperatures defined. If the airflow rate through the opening is zero then you will not be able to edit the data in the air temperature column.

Import EnergyPlus Boundary Conditions

You can import data that have been calculated in a previous EnergyPlus simulation as boundary conditions for the CFD simulation. The data that can be imported is:

- Surface inside temperatures of walls, floors, roofs, partitions, ceilings, windows, doors and sub-surfaces.
- Flow in and flow out of windows, vents, doors and holes (only when using the Calculated natural ventilation model option).

To import simulation data click on the **Import** button in the Boundary Conditions Editor (above).

Import Dialog

The Import data dialog allows you to select boundary conditions for a particular snapshot in time from the simulation results.

Interval

You can read CFD boundary conditions from either sub-hourly or hourly results. Select from:

- **1-Sub-hourly** where boundary condition data is loaded from sub-hourly EnergyPlus results.

- **2-Hourly** where boundary condition data is loaded from sub-hourly EnergyPlus results.

Time, Day, Month

Select the time and date to use for the import. The date must lie between the simulation start and end periods for the last simulation carried out.

Press OK to import the results to the CFD Boundary Conditions Editor.

When the **Interval** is set to **1-Sub-hourly** the times listed in the drop list will be in the format Hour:Minutes based on the currently set [Number of timesteps per hour](#). When the **Interval** is set to **2-Hourly** the time is simply the hour.

Note: all available opening airflow and inside surface temperature results from the most recent EnergyPlus simulation will be imported. That is the imported results are not restricted to the current CFD domain or zone (if this is a subset of the whole building).

Preparing Simulations To Generate CFD Boundary Conditions

You can use DesignBuilder simulations to generate boundary conditions for the CFD calculations. EnergyPlus simulations calculate the overall thermal behaviour of the building in terms of inside surface temperatures and natural ventilation flow rates then CFD allows you to 'zoom in' on the details of the temperature and flow distribution within the space for a particular snapshot in the simulation.

The simulation data that can be used as boundary conditions in CFD calculations are:

- Surface inside temperatures
- Natural ventilation airflow rates through external windows, doors, vents and holes.

To obtain access to the above data the simulation must generate inside surface temperatures and any natural ventilation airflow rates to be included in the CFD calculations. Before starting you should decide on the extent of the CFD domain and the time period you wish to analyse. Then only generate simulation data for these areas and time periods. Otherwise, for large models you might generate an impractical amount of data and overload the software.

The steps required to generate boundary condition data from simulation are:

1. If the CFD simulation is to use natural ventilation airflows through windows calculated by EnergyPlus then you must use the [Calculated natural ventilation](#) model option. [Scheduled](#) natural ventilation does not calculate airflows through individual windows.

2. Because CFD calculations do not use infiltration flows you may want to switch off [Infiltration](#) treatment on the [Constructions](#) model data tab. This will help ensure that the flow balance with little or no need for extra correction flows to be introduced on the [CFD Boundary Conditions](#) dialog. It also speeds up simulations by reducing the complexity of the Airflow network in EnergyPlus.
3. Switch off the [Lump similar windows on surface](#) model option to ensure that all windows are modelled individually.
4. Prepare the simulation model data and carry out test simulations to check that the model is behaving as expected during the period of interest (e.g. summer design conditions). Look at hourly results.
5. Navigate to the level in the model covering the CFD domain. If you are modelling a single zone in the CFD simulation, then navigate to that zone, if you are modelling a block then go that block or if you are modelling the whole building then go to building level. Then on the [Options](#) model data tab select the following output options:
 - **Store opening output** - ensure that data for windows, vents, doors, holes and sub-surfaces is included in the output.
 - **Inside Surface Temperature** - to store inside surface temperatures for all surfaces and openings in the domain.
 - **Airflow in** - to record the flow in through windows, vents, doors and hole (natural ventilation calculations only).
 - **Airflow out** - to record the flow out through windows, vents, doors and hole (natural ventilation calculations only).
6. Once the model is prepared, click on the Simulation tab and request **hourly** or **sub-hourly** results and run the simulation.
7. Check the simulation results by examining hourly results before feeding them into the CFD calculations. Check that airflow through windows is in the expected direction based on wind direction and expected wind pressures etc.
8. Start the [CFD Boundary Conditions Editor](#) and follow instructions for importing the simulation hourly or sub-hourly results
9. Add any assemblies or component blocks with any further boundary conditions needed to represent heat, temperature and flow boundaries imposed by HVAC, lighting and other equipment and occupants.
10. Make sure you have the same total convective heat from your internal gains in the CFD model as you had in the EnergyPlus simulation.
11. Check that CFD results correspond with the boundary conditions provided by the simulation.

Note: It is not currently possible to set flow boundary conditions on *internal* openings. So although EnergyPlus calculates flow rates through interior openings, DesignBuilder CFD will ignore these flows and re-calculate them using a more detailed method taking into account distributed air velocities and pressures. This means that the flows through internal openings calculated by the CFD won't match exactly with the flows calculated by the EnergyPlus Airflow network. EnergyPlus flow rates through *exterior* openings are always respected by DesignBuilder CFD when used as boundary conditions.

Note: [Infiltration](#) airflow is not modelled in CFD and if you are looking at summer time natural ventilation you may wish to switch Infiltration off in simulations. Winter time simulation may need infiltration included if it is significant.

Infiltration In CFD

DesignBuilder CFD doesn't include the concept of infiltration as cracks cannot be graphically defined and there can be no porous airflow through CFD surfaces as there can in EnergyPlus. Because airflow through cracks in simulations using [Calculated natural ventilation](#) can be significant, [importing](#) EnergyPlus opening airflows from simulations that include crack leakage can sometimes cause flow balance problems, especially in zones with only a single opening. It is therefore usually advisable to exclude the effects of [infiltration](#) from simulations that are to be used for setting boundary conditions for CFD. A warning message to this effect is given if you attempt to import simulation data generated using Calculated natural ventilation and infiltration.

Another reason for excluding infiltration from simulations to be used for setting up CFD boundary conditions is that the flow is likely to [balance](#) much more easily without the need to add large balancing flows to one or more openings.

Assembly Library

DesignBuilder is provided with an assembly library which contains a small database of typical components that may be useful in defining a CFD model. Some assemblies in the library include thermal gains while others simply provide an obstruction to airflow.

Add Assembly To Library

You can add your own assemblies to the model assembly library by selecting one or more component blocks when at building or block level and using the **Add assembly to library** toolbar command (or **Edit > Add assembly to library** menu option). This causes the Drawing options panel in the bottom left of the screen to be opened. Here you can enter a name for the assembly and define any default boundary conditions.

Note: The boundary conditions selected here will act as default settings at assembly block level and will not override any hard-set attributes made within the constituent component blocks themselves.

The full process is as follows:

1. Select the component blocks and/or CFD fans to be included in the assembly at block or building level. It does not matter which of these levels the blocks are originally created at. It will be possible to import the resultant assembly at building or block level regardless of where it was created.
2. Click on the **Add assembly to library** toolbar command.
3. In the Drawing options panel enter a unique name for the assembly and the default assembly boundary conditions.
4. Select the [Assembly creation mode](#).
5. Move the mouse to highlight the plane of the assembly to be used as the attachment plane and click. The **attachment plane** will be used later when placing the assembly.
6. Then click again to define the **attachment point** on the attachment plane. This will be the point that will be used to define the actual position of the assembly when it is placed later.
7. Click again to add the assembly to the library.

Assembly creation mode

Select from 3 options:

- **1-Replace with assembly instance** - the selected component blocks will be replaced by the new assembly.
- **2-Leave component blocks** - the selected component blocks are left unaffected by the creation of the new assembly.
- **3-Delete** - the selected component blocks are deleted once the new assembly has been created.

Export/Import

The assembly library data can be exported for use in other projects using the **File > Export > Export assembly library** menu command.

The exported assembly library .asl file can be loaded into other projects using the **File > Import > Import assembly library** menu command.

See also:

- "Assembly Block" on page 207
- "Component Blocks & Assemblies as CFD Boundaries" on page 1924

Updating The Assembly Library

From time to time new assemblies are added to the DesignBuilder assembly library and these new assemblies will be available when a new model is created with the new version of the software. However, previous models do not include newly added assemblies by default. To update the assembly library in an older model, follow the steps below.

1. Open the model requiring the updated library.
2. Select the **Import > Import assembly library** menu command.
3. Select the **system.asl** library file that is included in the default import folder (below).

The assembly library in your loaded project should now be up to date with the latest library provided with the software.

Detailed Equipment

Equipment tab in model data (*zone level only*)

Warning: This option is intended for modelling existing buildings where individual items of equipment have been recorded as part of a detailed survey and is not intended for general design or assessment simulation work.

When the [Gains model option](#) is set to **Detailed** you can enter data on individual items of equipment in each zone.

[Details on editing Equipment data](#)

Note: For other modelling applications you should use the [Early gains model option](#) because data can be set at the building level and/or loaded from template with much less effort.

Number	Rated power ...	Schedule	Radiant fraction	Latent fraction	Fraction heat lost
Computer accessories					
1	0,0000	On	0,10	0,00	0,00
Computers					
10	150,0000	8:00 - 18:00 ...	0,10	0,00	0,00
Fluorescent lights					
36	32,0000	On	0,10	0,00	0,05

Edit Equipment

[Detailed gains](#)

Use this screen to edit the equip for the current zone

With 'Detailed' gains detail, info each item of energy using equip its' operation is listed in detail.

This mode must be used with 7/ Operation Schedules.

[Add equipment](#)

[Edit selected equipment](#)

[Delete selected equipment](#)

Edit Detailed Equipment

You can model time-varying internal gains and energy consumption of individual items of equipment in each zone by adding equipment data at the zone level on the [Equipment tab](#). To add an item of equipment click on the Add toolbar icon, or if you are running DesignBuilder in Learning mode you can use the link in the Info panel to the right of the screen. This opens the **Edit Equipment** dialog.

You can define the category of internal gain (below), the number of items of equipment, the rated power per item of equipment as well as the operational schedule.

The **Radiant fraction** is the fraction of heat emitted by the device as long-wave radiation. The rest of the heat is considered to be convective i.e. it is modelled as heating up the zone air directly.

The **Latent fraction** is the fraction of the rated power which is converted to latent energy and affects the moisture balance in the zone instead of the sensible heat balance.

A number of categories of gains are available. These are listed below together with the output data with which they are associated:

- **Fluorescent lights** - General lighting
- **Tungsten lights** - Task lighting
- **Office equipment** - Computer + equipment
- **Computers** - Computer + equipment
- **Computer accessories** - Computer + equipment
- **Telecoms** - Computer + equipment
- **Lifts** - Miscellaneous
- **Catering** - Catering
- **Small power** - Miscellaneous
- **Heating** - Miscellaneous
- **Cooling** - Miscellaneous
- **Pumps** - Miscellaneous
- **Fans** - Miscellaneous
- **DHW** - Miscellaneous.
- **Process** - Miscellaneous
- **External lighting** - Task lighting

- **Other external** - Miscellaneous
- **Miscellaneous** - Miscellaneous

Note that all of the above gains are modelled as scheduled gains in the zone and the data is reported as such in the program output. So for example categorising an item of equipment as DHW does not affect in any way [DHW modelling](#) as defined on the [HVAC tab](#). Likewise data for Heating, Cooling, Pumps and Fans is simply modelled as a scheduled gain in the zone, completely unconnected with HVAC modelling.

Cost Data Overview

This page provides an overview of the various sources of data used in a building construction cost summary calculation.

The capital cost of constructing the building is defined in a number of places in the model:

1. Within the building model on component dialogs:
 - a. [Construction](#) - cost of constructions
 - b. [Material](#) - cost of material layers (cost per area or volume),
 - c. [Glazing](#) - cost of glazing systems (cost per window area)
 - d. [Window shading devices](#) such as blinds and shades (cost per window area)
 - e. [Local shading](#) such as overhangs and louvres (cost per window area)
 - f. [Wind turbines](#) connected to Load centres.
 - g. [Renewable generation distribution and electrical costs](#) from Load centres.

and on model data tabs:

- a. [Constructions](#) - sub-structure, structure and surface finishes.
 - b. [Lighting](#) - cost of lighting systems (cost per GIFA)
 - c. [HVAC](#) - cost of HVAC systems (cost per GIFA or capacity)
2. Building cost summary data on the [Building Cost Summary](#) dialog (accessed from [Tools](#) menu).

This data together with the building geometry allows the construction cost (aka capital expenditure or Capex) of the building to be calculated.

A [report of the cost](#) can be viewed on the Cost and Carbon screen.

Tip: The Capex totals can also be used as objective or constraints within optimisation or parametric studies.

Note: The costs provided in DesignBuilder's library databases were derived from a range of sources, including consultations with a professional cost modeller, published materials and extrapolation. They are intended to be indicative only and a starting point for users to build their own project and region-specific cost data sets.

1. Super-Structure And Sub-Structure Costs

In general the sub-structure cost is the cost of all works below ground level and super-structure cost is the cost of all works above ground level.

Opaque wall, roof, floor and partition fabric costs are calculated using the model geometry, and construction selected for each surface. The cost of each surface is calculated from its area and the type of construction

used. For an external wall the cost for a surface is calculated from its surface area (minus the area of any windows and other openings) and the cost of the construction per area. The cost of the construction per area is calculated in the way defined on the [Cost tab](#) for the construction.

Note: If a construction has more below ground surface area than above ground surface area, then this construction is defined as a below ground construction.

Glazing costs are calculated using the model geometry, the window areas and the glazing selected for each window. The cost of each window is calculated from its area and the type of glazing used. The cost of the glazing per area is defined on the [Cost tab](#) for the glazing component.

Note: For costing purposes the Roof/wall transition angle is assumed to be a fixed 70°, which mean if the slope is greater than 70°, then it is defined as a window, otherwise it is defined as a skylight.

Sub-structure costs are calculated as the sum of the [Sub-structure settings](#) on the Constructions tab and the construction costs of below-grade surfaces.

2. Building Cost Summary Data

You can access the extra building cost summary data on the [Building Cost Summary](#) dialog which is accessed from the Tools menu.

Building Cost Summary Data

The Building Cost Summary data dialog is accessed from the [Tools menu](#).

The dialog includes controls to allow you to select the cost calculation method. When either the NRM1 or UNIFORMAT II formats are selected, additional summary cost data for building can be entered to support the calculation.

Tip: The [Cost data](#) help topic provides an overview of the places in DesignBuilder where costs are entered.

Cost model

Select the model to use from:

- **1-Basic** for a simple report including only building construction costs.
- **2-UNIFORMAT II** for a summary cost report based on the standard ASTM UNIFORMAT II format.
- **3-NRM1** for a summary cost report based on the standard RICS New Rules of Measurement 1 format.

Calculation method

HVAC calculation method options are:

- **1-Cost per area** where the cost of the HVAC system is defined per floor area where typical only data is available.
- **2-Cost per capacity** where the cost of the HVAC system is defined per heating and/or cooling capacity of the zone HVAC system. This is normally a more realistic method given the right cost data. It requires the heating and cooling design calculations to have been previously carried out before cost reports can be provided. In the case of optimisation studies HVAC heating and cooling capacities are determined from the main simulation design sizing outputs.

UNIFORMAT II

UNIFORMAT II is one of the most widely used element-based classification standards in North America. Developed through an industry and government consensus, the standard is intended to reduce the effort in construction planning, scheduling and cost estimation in early design phases. Using it helps to ensure consistency in the economic evaluation of building projects over time and from project to project. It also enhances project management and reporting at all stages of the building life cycle—planning, programming, design, construction, operations, and disposal.

Elements are classified in three hierarchical levels of definition. Level 1 identifies seven Major Group Elements, such as the Substructure, Shell, and Interiors. Level 2 further subdivides Level 1 into Group Elements. The Shell, for example, includes the Superstructure, Exterior Closure, and Roofing. Level 3 breaks the Group Elements further into Individual Elements. Exterior enclosure, for example, includes Exterior Walls, Windows, and Exterior Doors.

Note: While DesignBuilder requires most of its data to be input using **Level 2** elements, it reports costs using both Level 1 and 2 formats.

Building and sitework elemental costs are presented with cost analysis parameters providing an efficient tool for communicating economic information to decision makers in a quickly understood, concise format that helps them make project choices. Owners, developers, programmers, cost planners, project managers, schedulers, architects and engineers, operating and maintenance staff, manufacturers, specification writers, and educators use the classification.

A major benefit of performing an economic analysis based on an elemental framework rather than on a product-based classification is the reduction in time and costs for evaluating alternatives at the early design stage. This encourages more economic analyses and more economically efficient choices among buildings and building elements. Other UNIFORMAT II benefits include providing a standardized format for collecting and analyzing historical data for use in estimating and budgeting future projects; providing a checklist for the cost estimation process as well as the creativity phase of the value engineering job plan; providing a basis for training in cost estimation; facilitating communications among members of a project team regarding the scope of work and costs in each discipline; and establishing a database for automated cost estimating.

The latest version of the UNIFORMAT II standard can be purchased at: <https://www.astm.org/Standards/E1557.htm> and a useful report from NIST - [NISTIR 6389](#).

The data that is not already included in the model should be entered on the UNIFORMAT II tab of this dialog. Much of the data is structured as a cost per area or per each followed by the area or the number of items in that category.

A Substructure

The [substructure costs](#) are defined in the model through use of zone cost per floor area data (A10) and the constructions themselves within the below grade constructions (A20):

- **A10 Foundation:** includes standard foundation, special foundations and slab on grade. The area used in the calculation is the ground floor area.
- **A20 Basement construction:** includes basement excavation and basement walls.

B Shell

The cost of the superstructure is defined within the model through the area of the various exterior surfaces making up the superstructure and the cost per area of their constituent opaque and glazed constructions.

- **B10 Superstructure:** includes floor and roof construction
- **B20 Exterior enclosure:** includes exterior walls, [structure](#), windows and doors
- **B30 Roofing:** includes roof coverings and roof openings

C Interiors

The cost of interior construction (C10) is defined within the model through the area of the various surfaces making up the interior construction and the cost per area of their constituent opaque and glazed constructions.

C10 Interior construction: includes partitions, interior doors and fittings

C20 Stairs: includes stair construction and stair finishes

C30 Interior finishes: includes wall finishes, floor finishes and ceiling finishes

D Services

Note that [HVAC costs](#) (D30) are included in the model.

D10 Conveying: includes elevators, lifts, escalators, moving walks and other conveying systems

D20 Plumbing: includes plumbing fixtures, domestic water distribution, sanitary waste, rain water drainage, and other plumbing systems

D30 HVAC: includes energy supply, heat generating systems, cooling generating systems, distribution systems, terminal & package units, controls and instrumentation, systems testing & balancing and other HVAC systems and equipment. This data is included zone by zone in the model on the [HVAC tab](#) and so does not need to be entered again here.

D40 Fire protection: includes sprinklers, standpipes, fire protection specialities and other fire protection systems.

D50 Electrical: includes electrical service & distribution, lighting & branch wiring, communication & security and other electrical systems.

E Equipment And Furnishings

E10 Equipment: includes commercial equipment, institutional equipment, vehicular equipment and other equipment

E20 Furnishing: includes fixed furnishings and movable furnishings

F Special Construction And Demolition

F10 Special construction: includes special structures, integrated construction, special construction systems, special facilities, special controls and instrumentation. Renewables costs, ([PV panels](#), [distribution and electrical](#), solar hot water systems and wind turbines) are included here.

F20 Selective building construction: includes building elements demolitions and hazardous components abatement.

G Sitework And Utilities

G10 Site preparation: includes site clearing, site demolition and relocations, site earthwork and hazardous waste removal/remediation.

G20 Site improvements: includes roadways, parkings lots, pedestrian paving, site development and landscaping.

G30 Site mechanical utilities: includes water supply, sanitary sewer, storm sewer, heating distribution, cooling distribution, fuel distribution and other site mechanical utilities.

G40 site electrical utilities: includes electrical distribution, site lighting, site communications & security and other site electrical utilities

G50 Other site construction: includes service and pedestrian tunnels and other site systems.

Z General Requirements And OH And P

Z10 Design allowance: cost of design work.

Z20 Field Requirements, office overhead & profit: includes field requirements and office overhead & profits

Z30 Inflation allowance.

NRM1

Published by the Royal Institute of Chartered Surveyors (RICS), NRM1 provides guidance on the quantification of building works for the purpose of preparing cost estimates and cost plans. It is described by RICS as the cornerstone of good cost management of construction projects, enabling more effective and accurate cost advice to be given to clients and other project team members, as well as facilitating better cost control. It helps by providing a standard format and sequence for priced works for the purpose of providing best practice guidance on the preparation of order of cost estimates, elemental cost models, cost plans, cost analyses and benchmark analyses.

The latest version of this standard can be downloaded from the [RICS website](#).

The data that is not already included in the model should be entered on the NRM1 tab of this dialog. Much of the data is structured as a cost per area or per each followed by the area or the number of items in that category.

Facilitating Works

- **Toxic / hazardous / contaminated material treatment:** Includes toxic or hazardous material removal, contaminated land and eradication of plant growth
- **Major demolition works:** Includes demolition works and soft strip works, temporary support to adjacent structures
- **Specialist groundwork's:** Includes site dewatering and pumping, soil stabilisation measures and ground gas venting measures
- **Temporary diversion works**
- **Extraordinary site investigation works:** Includes archaeological investigation, reptile / wildlife mitigation measures and other extraordinary site investigation works.

Substructure

The [substructure costs](#) are defined in the model through use of zone cost per floor area data and the constructions themselves within the below grade constructions.

- **Substructure:** Includes standard foundations, specialist foundations, lowest floor construction, basement excavation and basement retaining walls

Superstructure

The cost of the superstructure is defined within the model through the area of the various exterior surfaces making up the superstructure and the cost per area of their constituent opaque and glazed constructions. The exception is the stairs and ramps cost which is entered on this dialog.

- **Frame:** Includes steel frames, space frame / decks, concrete casings to steel frames, concrete frames, timber frames or specialist frames
- **Upper floors:** Includes floors, balconies and drainage to balconies.
- **Roof:** Includes roof structure, roof coverings, specialist roof systems, roof drainage, rooflights, skylights and openings.
- **Stairs and ramps:** Includes stair/ramp structures, stair/ramp finishes and stair/ramp balustrades and handrails.
- **External walls:** Includes external enclosing walls above ground level, external enclosing walls below ground level, solar/rain screening, external soffits, subsidiary walls, balustrades, proprietary balconies and facade access/cleaning systems
- **Windows and external doors:** Includes external windows and external doors.
- **Internal walls and partitions:** Includes internal walls, partitions, balustrades and handrails, moveable room dividers and cubicles
- **Internal doors**

Internal Finishes

[Internal finishes data](#) is entered for each surface using inheriting defaults on the Constructions tab.

- **Wall finishes**
- **Floor finishes:** includes finishes to floors and raised access floors
- **Ceiling finishes:** includes finishes to ceilings, false ceilings and demountable suspended ceilings (**be careful not to double count this in the construction costs**).

Fittings, Furnishings And Equipment

- **Fittings, furnishings and equipment:** includes general, domestic kitchen and special purpose fittings, furnishings and equipment. In addition, it also includes signs or notices, works of art, non-mechanical and non-electrical equipment, internal planting and bird and vermin control.

Services

- **Sanitary installation:** includes sanitary appliances, sanitary ancillaries
- **Service equipment**
- **Disposal installations:** includes foul drainage above ground, chemical, toxic and industrial liquid waste drainage and refuse disposal
- **Water installations:** includes main water supply, cold and hot water distribution, local hot water distribution and steam and condensate distribution
- **Heat source**
- **Space heating, air conditioning and ventilation (HVAC):** includes central heating, local heating, central cooling, local cooling, central and local air conditioning, central and local ventilation, special ventilation and smoke extract or control.
- **Electrical installations:** includes electrical mains and sub-mains distribution, power installations, lighting installations, specialist lighting installations, local electricity generation systems and earthing and bonding systems
- **Fuel installations:** includes fuel storage and fuel distribution systems
- **Life and conveyor installations:** includes lifts and enclosed hoists, escalators, moving pavements, powered stairlifts, conveyors, doc levellers and scissor lifts, cranes and unenclosed hoists, carlifts, car stacking systems, tumtables and the like, document handling systems and life and conveyor systems.
- **Fire and lightning protection:** includes fire fighting systems, fire suppression systems and lightning protection
- **Communication, security and control systems:** includes communication systems, security systems and central control/building management systems
- **Specialist installations:** includes specialist piped supply installations, specialist refrigeration systems, specialist mechanical installations and specialist electrical/electronic installations.
- **Builder's work in connection with service**

Complete Buildings And Building Units

- **Prefabricated buildings and building units:** includes complete building, building units and pods

Work To Existing Buildings

- **Minor demolition works and alteration works**
- **Repairs to existing services**
- **Damp-proof courses/fungus and beetle eradication**
- **Facade retention**
- **Cleaning existing surfaces:** includes cleaning existing surfaces and protective coatings to existing surfaces.
- **Renovation works:** includes masonry repairs, concrete repairs, metal repairs, timber repairs and plastic repairs.

External Work

- **Site preparation works:** includes site clearance and preparatory groundworks
- **Roads, paths, pavings and surfacing:** includes roads, paths and pavings, special surfaces and pavings.
- **Soft landscaping, planting and irrigation systems:** includes seeding and turfing, external planting and irrigation systems
- **Fencing, railings and walls:** includes fencing and railings, walls and screens, retaining walls, barriers and guardrails
- **External fixtures:** includes site/street furniture and equipment and ornamental features
- **External drainage:** includes surface water and foul water drainage, ancillary drainage systems, external chemical, toxic, industrial liquid waste drainage and land drainage
- **External services:** includes water main supply, electricity mains supply, external transformation devices, electricity distribution to external plant and equipment, gas main supply, telecommunications and other communication systems, external security systems, external/street lighting systems, local/district heating installations, builder's work in connection with external services.
- **Minor building works and ancillary buildings**

Main Contractors Preliminaries

- **Employer's requirements:** includes site accommodation, site records and completion and post-completion requirements
- **Main contractor's cost items:** includes management and staff, site establishment, temporary services, security, safety and environmental protection, control and protection, mechanical plant, temporary works, site records, completion and post-completion requirements, cleaning, fees and charges, site services, insurance, bonds, guarantees and warranties.

Main Contractor's Overhead And Profits

- Main contractor's overheads
- Main contractor's profits

Project Design Team Fee

- **Consultant's fees:** includes project/design team consultants' fees or other consultants' fees, site investigation fees and specialist support consultants' fees
- **Main contractor's pre-construction fees:** includes management and staff, specialist support services fees, temporary accommodation, services and facilities charges, and main contractor's overheads and profits.
- **Main contractor's design fees:** main contractor's design consultant's fees
- **Other development/project costs:** includes land acquisition costs, employer finance costs, fees, charges, planning contributions, insurances, archaeological works, other specialist fieldwork, decanting and relocation costs, tenant's costs/contributions, marketing costs and other employer costs.

Risk Allowance Estimate

- **Design development risks**
- **Construction risks**
- **Employer change risks**
- **Employer other risks**

Inflation Allowance

- **Tender inflation**
- **Construction inflation**

Model Data Management

Tools are provided to help manage the building model:

- "Model Data Grid View (MDGV)" on page 658 - view and edit model data in a grid
- [Load Data from Template](#) - load predefined data sets to the model from a template
- "Save Data to Template" on page 691 - save model data to create a new template
- "Reload Templates" on page 693 - reload any "hard-selected" templates, i.e. those shown in red on the model data user interface
- [Clear Data to Default](#) - clear data back to default values inherited from level above in model hierarchy)
- [Merging Zones](#) - control merging of zones from one dialog
- [Load Whole Building Infiltration](#) - load measured results from pressurisation tests

Model Data Grid View (MDGV)

Accessed from [Tools](#) menu

The **Model Data Grid View** (MDGV) tools allow the model data for the current building to be viewed and/or edited using a grid. It is possible to select from a range of "layouts" which define which data is to be displayed.

Viewing the building model data in a grid provides a global view of the data across the whole model and makes comparisons between settings for different parts of the model much easier than when using the usual model data input screen.

See also the [Model Data Grid View & QA checking](#) tutorial

Management Dialog

The MDGV tools are all accessed from the main **Model Data Grid View Management** dialog which is launched from the  toolbar icon or from the [Tools](#) menu and is active for the current building in the model. The Model Data Grid View tools can be accessed from building level and below, but are not available from site level.

The title of the dialog identifies the currently selected analysis type. The dialog presents a list of layouts which are:

- Filtered to those that are compatible with the current model's currently selected [Analysis type](#).
- Grouped by the level for at which they display data e.g. Building, Zone, Surface, Opening.
- Indicated as "System" or "User" under the **Layout Type** column.

The management dialog provides tools to access 2 different areas of functionality:

- [Model Data](#) – with **View** / **Edit** / **Import** buttons which can be used to access the model data itself.
- [Layout Management](#) – with **New** / **Edit** / **Copy** / **Delete** buttons which can be used to manage and modify the layouts, i.e. the definitions of which model data is to be shown.

You can use the Model Data Grid View tools to view and edit model data for the following objects:

- Buildings
- Building blocks
- Component and assembly blocks (at building and block levels)
- Zones
- Surfaces
- Openings

- All HVAC loops and components

The "building" model data is accessed by clicking on the **Building** tab. This lists all of the above layouts apart from the HVAC components as shown in the screenshot below.

For example, to edit window model data in the grid, click on the "External Glazing" layout and then click on the **Edit** button under the blue Model Data header in the top right.

The text in the **Layout Type** column (see above screenshot) flags whether the layout was provided by DesignBuilder with the program ("System"), or whether it is a custom layout created by the user ("User").

The HVAC data is accessed by first clicking on the **HVAC** tab to list available layouts.

You can choose to list only the HVAC components present in the model by checking the checkbox above the list. It is checked by default. Otherwise all available layouts are listed even if the corresponding components are not in the model.

For example, to edit the air loops in the grid, click on the "Air Loop" layout and then click on the **Edit** button under the blue Model Data header in the top right.

For more details on Model Data Grid View see:

- "Model Data Grid View - Viewing and Editing Model Data" on page 660
- "Model Data Grid View - Importing Model Data" on page 671
- "Model Data Grid View - Layout Management" on page 673
- "Model Data Grid View - Layout Editing" on page 676

Model Data Grid View - Viewing And Editing Model Data

Layout Selection

One or more layouts can be selected from the Layouts list on the Management dialog. When multiple layouts are selected the sum of all attributes from each layout is used to determine which model data will be presented.

Multiple layout selection is achieved using the <Ctrl> key and selecting additional layouts under the same level grouping. To select multiple layouts for viewing / editing they must be under the same level grouping, e.g. **Zone**.

Launching The View/Edit Grid Dialog

Once selected, model data for the chosen layout(s) can be viewed or edited by clicking the **View** or **Edit** button under the **Model Data** header on the **Model Data Grid View Management** dialog. This causes the selected model data to be loaded into the Model Data Grid dialog.

The only difference between view and edit modes is that in edit mode the data can be edited, while in view mode it cannot. The section below explains how to switch between the two modes.

The dialog title identifies the chosen layout (the first chosen layout and "... " if more than one layout was chosen). Below is an example of the data grid view created from selecting 2 layouts at Zone level:

Zone HVAC... [Read Only]

Core rooftoplight > Cor...	---	---	---	---	---	---	---	---	---	---	---	---	---

Switching Between Edit and View Modes

In the top left of the data grid dialog is the **Edit** checkbox. When the data grid is in edit mode this is checked. It can be unchecked and the data grid will be in view mode in which case data can no longer be edited. If any edits had been made prior to switching to View mode you will be prompted to establish whether the edits should be applied or discarded.

Columns left of the fixed splitter

Depending on the level grouping the layout belongs to there will be a set amount of viewable data on the left hand side of the data grid view and default grouping detailed as below:

Level	Set Data	Default Grouping
Site	Site Name	None
Building	Building Name	None
Block	Block Name	None
Zone	Zone Name	Block
Surface	Surface Name, Type, Area, Orientation, Slope	Block, Zone
Opening	Type, Adjacency, Area, Orientation, Slope	Block, Zone, Surface

A "splitter" separates the set data and model data attributes on the data grid view.

	Activity
	Floor Areas and Volumes
Zone	Floor area (m2)

The grid view header has 3 rows of header information:

- Attribute caption, e.g. "Outside air (ac/h)",
- Parent header caption for that attribute provides the context, e.g. "Mechanical Ventilation"
- Model data tab header, e.g. "HVAC".

For example:

Activity	HVAC		
Floor Areas and Volumes	Mechanical Ventilation		
Floor area (m2)	On	Outside air definitio...	Outside air (ac/h)

Showing / Hiding Data Grid Columns

For each of the 3 levels of header information described above it is possible to show and hide columns by right clicking on a column.

Group Level

At the “tab” level the top most grouped header will show / hide columns including parent headers and attribute headers beneath:

Activity	
Floor Areas and Volumes	✓ Activity ✓ HVAC ✓ Lighting
Floor area (m2)	

At the parent grouped header level the 2nd header will show / hide columns including attribute headers beneath:

Activity	
Floor Areas and Volumes	✓ Floor Areas and Volumes - HVAC Template ✓ Mechanical Ventilation - Operation - Economiser (Free Cooling) - Heat Recovery - Heating - Operation - Cooling - Operation - Humidity Control - DHW - Water Temperatures ✓ Operation ✓ Lighting Template ✓ General Lighting ✓ Lighting Control ✓ Lighting Area 1 ✓ Lighting Area 2 ✓ Task and Display Lighting
Floor area (m2)	
239.6	
239.6	
239.6	
239.6	
101.6	
44.8	

Individually

At the attribute header level the 3rd header will show / hide individual attribute columns:

Construction Template	Construction
Template	External walls
	Zone
	Block
	✓ Type
Project construction	✓ Area (m2)
Project construction	✓ Orientation (°)
Project construction	✓ Slope (°)
Project construction	✓ Template
Project construction	✓ External walls
Project construction	Below grade walls
Project construction	Flat roof
Project construction	Pitched roof (occupied)
	Pitched roof (unoccupied)
	✓ Internal partitions
Project construction	Semi-exposed walls
Project construction	Semi-exposed ceiling
Project construction	Semi-exposed floor
Project construction	✓ Ground floor
Project construction	✓ Basement ground floor
Project construction	✓ External floor
Project construction	✓ Internal floor

Grouping by Column

Grouping of attribute columns can be achieved by dragging the desired column into the grouping row:

Block			
Activity - Occupancy - Schedule			
			Activity Template
Zone	Template	Zone type	Zone multiplier
[-] 1F first floor East (1 item) ▶			
[-] 1F first floor East ▶ Office_OpenOff_Occ (1 item) ▶			
Open office	Generic Office Area	1-Standard	1
[-] 1F first floor West (1 item) ▶			
[-] 1F first floor West ▶ Office_OpenOff_Occ (1 item) ▶			
Open office	Generic Office Area	1-Standard	1
[-] 0F ground floor West (1 item) ▶			
[-] 0F ground floor West ▶ Office_OpenOff_Occ (1 item) ▶			
Open office	Generic Office Area	1-Standard	1
[-] 0F ground floor East (1 item) ▶			
[-] 0F ground floor East ▶ Office_OpenOff_Occ (1 item) ▶			
Open office	Generic Office Area	1-Standard	1
[-] Core circulation (1 item) ▶			
[-] Core circulation ▶ Office_Circulation_Occ (1 item) ▶			
Circulation	Office_Circulation	1-Standard	1
[-] Atrium Reception (1 item) ▶			
[-] Atrium Reception ▶ Office_Reception_Occ (1 item) ▶			
Reception	Office_Reception	1-Standard	1

Filtering

Rows in the data grid can be filtered. By hovering the mouse pointer at the right-hand side of the attribute column caption a drop down arrow will appear and clicking this will display the filter control:

Zone	Template	Zone type	Zone multiplier
1F first floor East (1 item)	Clear Filters (Select All) ☒ Generic Office Area ☐ Office_Circulation ☐ Office_Reception		
1F first floor East	Office_OpenOff_Occ (1 item)		
Open office	Generic Office Area		
1F first floor West (1 item)			
1F first floor West	Office_OpenOff_Occ (1 item)		
Open office	Generic Office Area	1-Standard	1
0F ground floor West (1 item)			
0F ground floor West	Office_OpenOff_Occ (1 item)		
Open office	Generic Office Area	1-Standard	1

More than one filter can be set up on different columns and can be cleared individually, or all at once, by clicking the **Clear Filters** button.

Tip: By setting appropriate filters, and using the bulk edit facilities, you can make changes to only the objects that meet your selection criteria, effectively mimicking a search and replace operation.

Searching

At the top of the data grid is a search box. Any text entered here and matched in the data grid will be highlighted in a yellow/brown colour. Search matches can be navigated via the search up and down arrows. The "x" symbol closes the search box (cancelling the search), which can be re-opened by entering Ctrl+F on the keyboard.

Office_C							
Block Activity - Occupancy - Schedule							
Zone	Template	Zone type	Zone multiplier	Include zone in ther...	Include zone in Radi...	Occupancy density (...)	Schedule
Core circulation (1 item)							
Core circulation	Office_Circulation_Occ (1 item)						
Circulation	Office_Circulation	1-Standard	1	☒	☒	0.1100	Office_Circulation_Occ

Exporting data

The visible data grid view may be exported to a comma separated file (.CSV) for subsequent editing in another program, e.g. in MS Excel. Clicking the **Export** button will launch a dialog to specify the file name and choose its location.

Data in the exported CSV file can be edited in a spreadsheet tool, saved and [imported](#) back into the model.

Tip: To edit a CSV file that was exported by the Model data grid tool, simply double-click on it from Windows Explorer. Make sure to save the file in CSV form as well if you intend to import the data back into DesignBuilder.

Editing Data in a Grid Cell

In edit mode all data cells can be edited except for:

- Light yellow shaded:

- Grey non viewable box:

Grey non viewable boxed cells appear when:

- o The data is not relevant to view / edit e.g. activity, lighting and HVAC data for merged child zones.
- o The data is not appropriate to view / edit e.g. blocking out wall construction data for a floor or roof surface.
- o An attribute visibility rule defined in a layout fails the criteria for that rule. E.g. to provide a list of roof windows, a rule might check that the parent surface custom attribute Surface Type has a particular value to decide whether an opening is to be displayed.

Clicking in a selected cell will set it into editing state.

The following type of edits are available depending on the type of model data:

- **Numeric / Text** - Entered content will be validated against the type of model data being edited to ensure it is appropriate i.e. whole number, decimal etc.
- **List** – a drop down list of valid values will be shown to make a choice from:

Zone	Template	Zone type	Zone multi
1F first floor East (1 item)			
Open office	Generic Office Area	1-Standard	1
1F first floor West (1 item)			
Open office	Generic Office Area	1-Standard	1
0F ground floor West (1 item)			
Open office	Generic Office Area	1-Standard	1

- **Browse** – a browse dialog will appear to allow selection from categorised values, with the initial select value being defaulted to the current model data:

Colour Codes

The Model Data Grid View uses colours to provide extra information about the data.

Text colour

On the main model data dialogs DesignBuilder uses text colours to indicate which values are inherited from levels above in the model hierarchy using blue. Values that are hard set (i.e. not inherited) are displayed in red. A similar colour coding system is used in the Model Data Grid View. In general values that are hard set are shown in **red** and values that are inherited are shown in **blue**. There are a couple of differences in the grid though:

- Values that have been edited in the current grid edit session are shown in **red** (even before they have been saved to the model). All other values are shown in **blue**.
- Detailed HVAC objects don't use inheritance and so are treated differently. Data for HVAC objects is always displayed in **blue**, unless it has been edited in the current session.

Cell background colour

The cell background colour is generally white with the following exceptions:

- Cells with data that can be viewed but not edited are displayed with a light yellow background.

Air Loop OG2	2.64722
--------------	---------

- Cells that are not available for display or edit are shown with a grey background (see also above). In the case below the **Floor area per person** data cannot be edited if the zone is not occupied:

Occupied?	Floor area per perso...
☒	10.00
☒	10.00
☐	—
☐	—

- Rows that are selected are shown with a blue/grey background colour:

▶	Component block 3	1-Standard	☒	1-Building	Component block m...
---	-------------------	------------	-------------------------------------	------------	----------------------

- Rows that are selected for **Bulk edit** are displayed with a lavender background colour:

Building Component...	Component block ty...	Shades and reflects	Level	Material
Component block 1	1-Standard	☒	1-Building	Component block m...
Component block 2	1-Standard	☒	1-Building	Component block m...
Component block 3	1-Standard	☒	1-Building	Component block m...

- Rows that contain a search term typed into the **Search** bar at the top of the grid are shown in a dark yellow colour.

Copy & Paste

A selected data cell's content can be copied to the clipboard via <Ctrl>+C or a right click context menu:

Where the type of model data is appropriate to paste into a data cell the <Ctrl>+V or the Paste menu item will be available to paste what is on the clipboard.

Bulk Edit

Multiple rows on the data grid can be selected by holding down the <Ctrl> key and left mouse clicking additional rows for selection or by holding down the <Ctrl> key + <Shift> key and clicking rows below for contiguous selection.

When 2 or more rows are selected, the **Bulk Edit** check box towards the top left of the data grid dialog can be checked and bulk edit mode will be enabled for the selected rows with the currently editable rows becoming highlighted with a lavender (blue/purple) background colour:

☒ Edit

☒ Atrium Reception (1 item) ▶		
Reception	Circulation area (corridors and stairways)	1-Standard

Unchecking the **Bulk Edit** checkbox will return the data grid to its previous edit mode state.

Applying changes

Current changes may be applied to the model by clicking the “Apply” button. If there are changes yet to be applied and either the dialog is closed or Edit mode is switched back to view, there will be a confirmation dialog to determine what should happen next:

If switching from Edit mode to View mode and the “No” option is chosen the latest changes will be reverted to what is stored in the current model.

Note: Applying changes is not the same as saving the file. Any changes applied to the model still require the model file to be saved.

Grid Limitations

You should take care when making changes in the grid to ensure that you enter valid values or make valid selections. In the main model data user interface, irrelevant settings are hidden, drop lists and browse lists are configured to display only allowed values and numeric range checks are applied depending on the specific model settings and configuration. However the grid does not provide the same level of responsiveness and so, while the drop lists and browse lists will generally provide allowed settings, in some cases extra settings that do not apply will be displayed in the grid. If in doubt about which settings need to be edited please refer to the allowed values in the help and to the main model data user interface which is fully responsive to settings.

Using MDGV for Detailed HVAC Data

You should be especially careful with making changes to Detailed HVAC components some of which have complex rules to show/hide data based on other settings which have not yet implemented for the MDGV. More specifically, while the main HVAC component dialogs display only data that is relevant to selected options, the Grid edit HVAC views show *all* data settings regardless of whether they are relevant or not. The MDGV Layouts will be tidied in future to only show relevant settings, but in the meantime care is needed when using the MDGV for HVAC data to ensure that you are editing the right settings.

In summary, when using MDGV for adjusting Detailed HVAC settings please be aware that not all the HVAC data displayed in MDGV may be relevant to your model. Before editing you should:

1. Make sure you know which settings you wish to modify.
2. Modify the data for all similar components using MDGV.
3. Check at least 2 components using the popup dialogs from the main screen, to ensure that the new settings took effect as intended.

Model Data Grid View - Importing Model Data

You can import model data that was previously exported as a CSV file and subsequently modified in another application such as MS Excel or a text editor.

Selecting a file for import

Clicking the **Import** button on the management dialog will open a standard file selection dialog filtered to files with “.CSV” extensions only. When the required CSV file is selected and **Open** clicked the import process will commence.

Checks performed prior to import

A series of checks are performed prior to importing a CSV file.

Establish whether Site / Building identifiers match

A check is made to check whether site / building identifiers match. If this is not the case the following warning message dialog is displayed:

Choosing **No** will exit the import process. Choosing **Yes** will progress the import process to the next check.

Establish whether Model objects match

A check is made to establish whether model objects in the CSV file match with model objects in the current model. If model objects in the CSV are not found then the following warning message dialog is displayed:

Choosing **No** will exit the import process. Choosing **Yes** will progress the import process. The **Save** button saves the list of unresolved model objects to a text file for subsequent checking.

- The allowed [Analysis types](#) are EnergyPlus, SBEM, DSM.
- The model attributes to be displayed are Window height, Window width.

In the above example, the layout, when selected, would allow the Window height and width to be viewed for all openings in the model for any of the 3 main analysis types.

System layouts

System layouts are pre-defined layouts supplied with the software to cover aspects of building models considered to be of general purpose use for viewing / editing in a data grid.

User layouts

User layouts are those created by users to allow customised views of the model.

Management of Layouts

Management of layouts is performed on the Layout management dialog using the buttons under the **Manage Layouts** header.

The table below shows the actions that may or may not be performed on layout definitions:

Action / Layout type	System	User
New	No	Yes
Copy	Yes	Yes
Edit	No	Yes
Delete	No	Yes

Creating a Layout

Clicking **New** will launch the [Layout Editor](#) to allow a new User Layout definition to be created.

Editing a Layout

Clicking **Edit** will launch the [Layout Editor](#) to allow a User Layout definition to be modified. System layouts cannot be edited.

Copying a Layout

Clicking **Copy** will copy a selected System or User Layout . The new Layout is displayed under the appropriate model object type in the Layouts list.

Deleting a Layout

Clicking **Delete** will prompt for confirmation to delete the selected User Layout. System layouts cannot be deleted.

Exporting a Layout

When a user layout is selected, clicking **Export Layout** will open a standard file save dialog allowing for a choice of location and file name to be specified for the layout:

This allows you to export layouts for subsequent import on another machine.

Importing Layouts

Clicking **Import Layout** will open a standard file open dialog allowing for the selection of one or more user layout files to be imported:

Where there is a clash in layout name with existing layouts a new name is given. For example, if a layout named “Internal Doors” exists and a layout of the same name is imported it will be given the name “Internal Doors (1)”.

Model Data Grid View - Layout Editing

The Layout Editor dialog allows user-defined custom Layouts to be set up for use alongside the pre-defined layouts provided with the software. The Layout editor can be launched from the management dialog via the Manage Layouts > **New** and **Edit** buttons. On first opening the Layout Editor dialog will look something like this:

The screenshot shows the 'Layout Editor' dialog box. It features a 'Name' field at the top left. To its right are 'Analysis Types' (with checkboxes for EnergyPlus, SBEM, and DSM) and a 'Level' dropdown menu (set to Building). Below these is the 'Attributes' section, which contains a tree view of various attributes such as 'Activity - Activity Template', 'Construction - Construction Template', and 'Openings - Glazing Template'. To the right of the attributes tree is the 'Attribute Visibility Rules' section, which includes input fields for 'Object', 'Attribute', 'Comparison', and 'Value(s)'. At the bottom of the dialog are 'Help', 'OK', and 'Cancel' buttons.

There are 4 areas of data to be entered on the dialog:

- **Analysis types** which allows you to specify which Analysis types the layout applies to.
- **Level** which defines the data that will be displayed and editable (typically zone, surface or opening).
- The list of **Attributes** that can be displayed when the layout is accessed for view/edit.
- For each attribute any special **Visibility rules**.

These 4 areas are covered in more detail below.

When creating a new Layout, the **Analysis type** is set by default to match that of the current model's [Analysis type](#) (typically EnergyPlus, SBEM or DSM) and the **Level** is set to **Building**. The list of available attributes is based on the Analysis type and Level selections and will change when different combinations of Analysis types and level are selected.

Layout Details

Name

Enter a descriptive identification for the layout. This will be displayed on the list of Layouts on the main Model Data Grid View Management dialog.

Analysis Types

Select one or more analysis types to define which are compatible for the layout being defined. For example if your layout should only be available for EnergyPlus models for then check that checkbox only. In this case the Layout will appear in the Layout list on the main Model data grid view [management dialog](#) for models where the Analysis type is set to EnergyPlus. However, if your model is located in the UK and the Analysis type for your model is set to SBEM or DSM then this layout won't appear in the Layout list.

Level

Select the model object the layout will apply to. Options are:

- **Site,**
- **Building,**
- **Block,**
- **Zone,**
- **Surface,**
- **Opening.**

For example if you select the **Zone** level, the layout will display data for zones, i.e. each row in the model data grid view will be for a zone. In this case the attributes specified for each zone are defined as described below.

Attributes

The attributes to be displayed as columns in the model data grid view are defined by making appropriate selections in the list of attributes by checking the required attributes.

The attributes list is grouped into categories based on the model data tab in which it appears: Activity, Construction, Lighting, Outputs, CFD etc. The tree view nodes can be expanded to reach the required attributes which can have their respective checkboxes checked to select the attribute to be included with the layout. See below.

The attributes displayed in the list depends on the [Analysis types](#) and model object [Level](#) selected (see above).

If the Layout Editor was launched for an existing Layout via the **Edit** button from the Layout management group then the attributes to be displayed will have their respective check boxes checked.

Custom Attributes

To enhance the information presented on the data grid, some additional read-only attributes are included in the list depending on the data level. If custom attributes are available for the selected level they will appear at the bottom of the attributes list. Custom Attributes will always appear in the data grid, unless an attribute visibility rule has been defined to hide them in certain circumstances.

Committing / Cancelling Layout Edits

Clicking “OK” will create/update a new/existing Layout.

Clicking “Cancel” will return to Layout Management without saving changes.

Attribute Visibility Rules

When you select an attribute in the list on the left of the dialog, the settings in the [Attribute Visibility Rules](#) group on the right of the dialog are enabled and you can define a rule to customise the visibility of that attribute in the data grid. Visibility rules are set up to ensure that attributes are only displayed in the model data grid view where appropriate. Visibility rules work through a simple comparison using an attribute from a level higher up the hierarchy than the objects being displayed. There are 2 types of rules:

- **Column visibility** rules which check the value of a level attribute far enough up the hierarchy that the evaluation is the same for all objects (rows) to be displayed in the grid. This allows a whole column to be shown or hidden depending on the evaluation of the rule. Column visibility rules are based on building or site attributes. An example of a column visibility rule is where the visibility of the **Natural ventilation outside air flow rate** is to controlled based on the [Natural ventilation model option](#). Because this model option is a building level setting it applies equally to all zones (rows) in the grid and so the column can be hidden entirely if the Calculated natural ventilation model option is set.
- **Cell visibility** rules are checked separately for each row and control the visibility of individual cells. Individual cells are "hidden" by displaying a blank / grey data grid cell. An example of a cell visibility rule is one where the Glazing type is only shown for openings where the parent surface is of External wall surface type. Hidden cells are displayed as:

For both types of rule you may need to refer to some attribute option lists to help you define the visibility rules. Some commonly used attribute settings are listed below under [Attributes Commonly used in Visibility Rules](#).

Object

The **Object** selection determines which model object level will be used as the basis for the rule. Note that only levels "above" the level specified in the Layout level are available. For example if the layout [Level](#) is set to **Zone** then the only **Object** options allowed are Block, Building and Site.

Attribute

The **Attribute** to be used in the visibility rule can be chosen by clicking the browse button "... " to display the Attribute Browse dialog:

Attributes in this tree view are based on the selected model Object selected and the Analysis types as described above.

Custom attributes (if applicable for the selected model Object) are found at the bottom of the tree view.

Comparison

The comparison operator for the rule. Currently available options are:

- = equal to
- != not equal to
- < less than
- > greater than
- <= less than or equal to
- >= greater than or equal to

Value

The value to compare the chosen attribute value against. A range of values can be specified by separating with commas. E.g. 1,2,10. So, for example, for Model Object "Site" for attribute "Analysis Type" with a comparison on "=" and a value = "1,2,10" the rule will be passed if the current model's [Analysis type](#) is **1-EnergyPlus**, **2-SBem** or **10-DSM**.

Types of rule

Column visibility rules

A rule applied using a high level attribute will impact the visibility of the attribute for all objects in the grid, i.e. the column won't appear in the data grid. The example below shows the how the rule for the [Occupancy density](#) attribute is set up, based on the value of the [Occupancy method](#).

Attributes

- ▾ ☒ Attributes
 - ▾ ☒ Activity - Activity Template
 - ☒ Template
 - ☐ Sector
 - ☐ Sub building
 - ☒ Zone type
 - ☐ Unconditioned zone ventilation
 - ☐ Space condition category
 - ☒ Zone multiplier
 - ☐ Favoured orientation
 - ☒ Include zone in thermal calculations
 - ☒ Include zone in Radiance daylighting calculations
 - ▾ ☒ Activity - Floor Areas and Volumes
 - ☒ Floor area
 - ☒ Zone volume
 - ☐ Inner surface mode
 - ▾ ☒ Activity - Occupancy
 - ☒ Occupied?
 - ☒ Occupancy density
 - ☒ Number of people
 - ☒ Schedule
 - ☐ Occupancy
 - ☐ Days / week
 - ☒ Latent fraction

Attribute Visibility Rules

Object
Building

Attribute
Occupancy method

Comparison
=

Value(s)
1

Note: Column visibility rules use Site or Building level attributes such as [Analysis type](#) (a site level attribute) or building model options. An exception would be for a layout set up to list building level data for multiple buildings on the site in which case building attributes would not be an option and only site level attributes could be used.

Cell visibility rules

Rules applied at a lower level allow the visibility attributes to be controlled on a per object basis. For example the screenshot below shows a case where data grid cells are shown for the Roof Glazing type attribute for openings where the opening's parent [Surface type](#) has a value of 2, i.e. it is a pitched roof:

This rule results in a grid view similar to that shown below where the rule applied only allows the Roof glazing type to be shown for the 2 pitched roof windows:

Type	Adjacency	Slope (°)	Glazing type
Window	External	90.0	—
Window	External	90.0	—
Window	External	90.0	—
Window	External	90.0	—
Window	External	31.1	Project roof glazing
Window	External	31.1	Project roof glazing

Attributes Commonly Used In Visibility Rules

Analysis type

The [Analysis type](#) is a site level attribute set on the [Display tab](#) of the Model option options dialog defining the purpose of the analysis. It controls which user interface items, data, calculations and outputs are available.

Analysis type can be used for controlling the availability of entire layouts through use of the [Analysis types](#) checkboxes as described above or individual attributes through the [Attribute visibility rules](#).

The most common Analysis types are:

- **1-EnergyPlus** - the analysis type for general purpose simulation work.
- **2-SBEM** - for SBEM EPC and Building Regulations compliance calculations in the UK and Ireland at NOS levels 3 and 4. This option is only available when the site is located in the UK or Ireland.
- **7-RT2012** - for Building Regulations compliance calculations in France. This option is only available when the site is located in France.
- **10-DSM** - for DSM EPC and Building Regulations compliance calculations in the UK and Ireland at NOS level 5. This option is only available when the site is located in the UK or Ireland.

Surface type

It can be useful to show/hide opening level attributes based on the parent surface type. For example displaying **Glazing type** for surfaces of type 3 (walls). See above under [Cell visibility rules](#). The full list of surface types used internally by DesignBuilder is as follows:

- **0-Floor**
- **1-Flat roof**
- **2-Pitched roof**
- **3-Wall**
- **4-Hole**
- **8-Sloped floor**

Model Data Grid View Examples

General Steps

To use the MDGV tool follow these steps:

1. Click on the **Model data grid view** toolbar icon to open the main Management dialog.
2. If a Layout already exists that provides the data you need, select it from the list.
3. Otherwise, if you need to create a custom layout, expand the **Manage Layouts** header to view the options, then click on the **New** button to [create a layout](#).
4. Once you have selected a layout in the list click on either the **View** or the **Edit** button to load the requested model data to the grid.
5. This opens the main Model Data Grid View dialog, displaying the data requested in the Layout for viewing or editing. If you selected to view the data you can always enable editing later by checking the Edit checkbox at the top of the grid dialog.
6. To change data on multiple rows in the grid select the rows you would like to edit using the mouse together with the <Ctrl> or <Shift> keys and then check the **Bulk Edit** checkbox. This highlights the selected rows in blue and then any edits you make to one of the rows will be applied to all selected rows.
7. Once you have finished making changes click on the **Apply** button on the top right of the main grid to save your changes and close the dialog.

Detailed HVAC Example - Bulk Edit Fan Settings

This example shows how to edit the properties of all fans in a Detailed HVAC model.

1. Either load an existing Detailed HVAC model with multiple fans included, or create a new model with several zones, set the Detailed HVAC model option and load the "FCU 4-Pipe, Air Cooled Chiller" Detailed HVAC template for all zones.
2. Click on the **Model data grid view** toolbar icon to open the main Management dialog.
3. Select the **HVAC** tab at the top to view the HVAC Layouts.
4. Tick the **Show only HVAC components present in the model** checkbox to help you find the relevant HVAC Layouts.
5. Select the "Fan" Layout from the list.
6. Click on the **Edit** button to load the fan model data to the grid on the main Model Data Grid View dialog.
7. If you loaded the "FCU 4-Pipe, Air Cooled Chiller" Detailed HVAC template you will notice that all FCU fans have a Pressure rise setting of 100 Pa.
8. Select the fans you would like to edit using the mouse together with the <Ctrl> or <Shift> keys and then check the **Bulk Edit** checkbox. This causes the selected rows to turn blue/mauve as shown below.

Fan [Bulk Edit]

☒ Edit ☒ Bulk Edit

Search (Ctrl+F) ^ v X

Drag a column header here to group by that column.

General				
Name	Zone Group	Type	Fan total efficiency	Pressure rise (Pa)
BLOCK1:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	100.0
BLOCK2:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	100.0
BLOCK3:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	100.0
BLOCK4:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	100.0
BLOCK5:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	100.0
BLOCK6:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	100.0

9. Change the **Pressure rise** for one of the fans to 120 Pa and press <Enter>.

Note that all same change is automatically applied to all selected fans as shown below. Changed cells are shown with a turquoise blue background.

Fan [Bulk Edit]

☒ Edit ☒ Bulk Edit

Search (Ctrl+F) ^ v X

Drag a column header here to group by that column.

General				
Name	Zone Group	Type	Fan total efficiency	Pressure rise (Pa)
BLOCK1:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	120.0
BLOCK2:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	120.0
BLOCK3:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	120.0
BLOCK4:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	120.0
BLOCK5:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	120.0
BLOCK6:ZONE1 Fan...	Zone Group	3-On/Off	0.70000	120.0

10. Once you have finished making changes click on the **Apply** button on the top right of the main grid to save your changes and close the dialog.

Note: The above bulk edits could perhaps be made more easily using the **Target** tab on the Fan dialog for one of the fans, requesting the changes to be applied across the equivalent fans in the same HVAC zone group. However, for larger models with multiple zone groups or AHUs the MDGV method is generally be the most efficient way to make bulk edits.

Load Data From Template

Model Data Management

The **Load Data from Template** dialog allows bulk changes to be made by loading templates to selected locations in a model in a controlled way.

Access the Load Data from Template from:

1. The Toolbar
2. The Edit menu
3. [Mouse right-click in the Model data](#). In this case, by default, any template data loaded applies only to the selected model data attribute.

[Quick view](#) of the Load data from template tool in action

See also the [Glazing and openings](#) tutorial

You can select one or more data sources from the following template libraries:

- Construction template
- Glazing template
- Facade template
- Activity template
- Lighting template
- HVAC template

When at site level only one template can be loaded:

- Location template

When you select one of the above template libraries as a source of data you must also select the template from which to load:

In the above case, data will be loaded from the **Energy code - Mediumweight** Construction template to whichever objects are selected on the Target tab.

Target Objects

On the **Search** tab you can select how you want to set data and, where appropriate, which model objects to load to.

- **1-Selected objects** - choose this option if you want to load the same data to one or more building, block, zone or surface. Check the boxes next to the target objects to select them as targets.
- **2-Reload templates** - reloads template data for the current building and all its blocks, zones, surfaces and openings. Data is only loaded if the template selection is non-default. If the template inherits from the hierarchical level above, data is not loaded. See also [Reload Templates](#).
- **3-Search & replace** - allows you to search the model for objects having particular browse item selections and replace those settings with data from a template that you select.

Reload Templates

[Model Data Management](#)

The **Edit > Reload templates** menu command provides a quick way to reload template data for the current building and all its blocks, zones, surfaces and openings. Data is only reloaded if the template selection is non-default. If the template inherits from the hierarchical level above, data is not loaded. This ensures that any model data that was manually overridden reverts back to template settings. After running this command you should not see any model data shown in red bold.

The command opens the [Load data from template](#) dialog with the option **2-Reload templates** selected and all model data tabs selected for updating. You can modify these settings, for example if you only wish to reload data on certain model data tabs.

This option can be conveniently accessed from the [Edit](#) menu.

Tip: Reload templates can be run after overriding attribute data previously loaded from template to ensure that the latest template settings are used.

Search and Replace

The **Search and Replace** option allows you to search the model for objects having particular browse item selections and replace those settings with data from a template that you select. The tool works differently depending on whether the Load data from template dialog was opened from the toolbar or from the right-click context menu.

Tip: The [Model Data Grid View](#) includes [filter](#) and bulk edit tools that can be used to bulk edit models, and in most case, that is the preferred way to go about it.

Search and replace - accessed from the context menu

If you wish to search for particular browse option settings and replace them with alternative settings from a specific template, use the context menu by right-clicking on the browse item of interest and selecting the Search and replace ... option.

In the example above, the user right-clicked on the [Window shading type](#) browse item. Then, selecting the **Search and replace window shade** option opens the **Load Data from Template** dialog with the **3-Search &**

replace method selected. By default the search term is the currently selected object in the underlying browse item. In the above case, the currently selected Window shading type.

You can select the other objects that will be included in the search and replace operation using the checkboxes against the TreeView list under the **Search in** header below.

On the **Replace With** tab you can select the template(s) that will be used as a source for the replace data. Since the search and replace operation only applies to a single item when the dialog is accessed from the context menu, there is no point in selecting anything other than the Glazing template in this example as this is the source of the required Window shading type data.

Alternatively, you can select the **All** option on the **Replace With** tab and select any other templates that should be used as a source. In this case, any selected templates will be fully loaded to any model objects (blocks, zones, surfaces and windows) matching the search term. In our example, we will only select Glazing template.

Pressing the OK button causes the Window shading type setting from the Glazing template selected on the **Replace With** tab to be loaded to all model objects selected on the **Search** tab.

Search and replace - accessed from the toolbar/menu

In cases where you wish to load data from multiple templates for each selected object that meets your criteria, you can open the **Load Data from Template** dialog by clicking on the toolbar icon or from the Edit menu and set the Method on the Search tab to **3-Search and Replace**. When search and replace is accessed in this way, each template is handled individually. For example, if Activity template search is active (**Activity** is selected on the **Search For** tab) and, during the search processing a match is made with the selected Activity template on the **Search For** tab, then the Activity template selected on the **Replace With** tab will be used to replace it, regardless of any settings for Construction, Glazing, Facade templates etc.

In other words, for each object selected on the **Search** tab, the tool checks whether the **Activity** checkbox on the **Search For** tab is checked. If it is and the selected Activity below that is selected in model data for this object, then the selected activity on the **Replace With** tab is loaded to that object. Then a similar check is made for Construction, Glazing, Facade, Lighting and HVAC templates. Then the operation moves on the next object selected on the **Search** tab until all objects have been processed.

On the **Search** tab:

1. Select the **3-Search and Replace** Method.
2. Check the checkboxes to define the model data objects (blocks, zones, surfaces and windows) you wish to search.

On the **Search For** tab:

1. Check the checkboxes to enable you to select the items you wish to search for.
2. For example, in the screenshot below, the user wishes to load a new construction template for model objects that have the "TSBC_construction_template" selected. They also wish to load a new Glazing template for model objects that have the "TBSC_glazing_template" selected. And load a new Facade template for model objects that have the "No glazing" Facade template selected.

On the **Replace With** tab:

1. Note that the **All** model data setting is selected at the top of the dialog and greyed out, indicating that the process will replace all of the selected templates, as opposed to the case where Search and replace is accessed from the context menu when it applies to only to the selected attribute.
2. Check the checkbox is associated with the various template types to be loaded, and,
3. Select the required templates to be loaded.

When the OK button is pressed, for each model object selected on the **Search** tab, DesignBuilder checks to see whether all of the search conditions are satisfied as defined by selections on the **Search For** tab, and if they are, it loads all of the settings requested on the **Replace With** tab.

Selection tools

When on the **Search** tab, selection tools on the Info panel enable you to control the selection of building objects:

- **Select all** selects all objects in the navigator.
- **Select all down to zone level** selects all buildings, blocks and zones.
- **Select none** clears the selection.
- **Selection filter** opens the [Filter](#) selection dialog.

Tip: The [Filter](#) selection tool provides a convenient way to select multiple objects such as zones, surfaces and windows which have properties in common.

Load data from template - accessed from the context menu

When opening the dialog by right-clicking on a Model data item and selecting the **Load data from template** menu context menu option, by default any template data loaded applies only to the selected model data attribute, in the case below, the external glazing type. This behaviour can be changed by selecting the **All** Model data drop list option (screenshot below). In this case, when the **All** option is selected, data is loaded to all attributes on the tab in the same way as if the dialog had been opened from the Toolbar.

Making global lighting settings

If you are using the **2-Normalised power density** [Lighting gain units](#) model option

When you load lighting data from template you should bear in mind that DesignBuilder sets the lighting output from the lights based on:

- a. [Normalised power density](#) (W/m²-100 lux or W/ft²-fc) using data from the [Lighting template](#) and,
- b. [Illuminance levels](#) required in the zone as set on the [Activity tab](#).

If you are using the **3-Absolute zone power** [Lighting gain units](#) model option

If you have many types of activity in the building you can load lighting data for each zone taking into account the required illuminance level in the zone by selecting the appropriate zones in the Target tab.

Filter Selection

The Filter selection dialog provides tools to allow the selection of objects on the [Load data from template](#) dialog to be controlled. It is accessed by clicking on the Selection filter link in the Info panel of the Load data from template dialog.

Note: Selections made using this dialog are additive to any already made. To clear any previous selections first you should use the **Select none** option on the [Load data from templates](#) dialog before opening the Filter selection dialog.

See also the [Glazing and openings](#) tutorial

General

There are 3 general selection methods selected from the **Filter by** drop list:

- **1-Zones** - the filter tools will be used to select zones with particular text in their name or tag.
- **2-Surfaces** - the filter tools will be used to select particular surfaces.
- **3-Openings** - for selecting particular openings.

Adjacency selection

When either **2-Surfaces** or **3-Openings** are selected as the **Filter by** method you can define whether the selection should apply to internal, external or to both internal and external objects. Select from:

- **1-Internal** - select only internal surfaces/openings.
- **2-External** - select only external surfaces/openings.
- **3-Internal and External** - select both internal and external surfaces/openings.

Zones

When the **1-Zones** selection method is used you can filter either by zone name or tag.

Filter by zone name

If you wish to filter by the zone name then check this checkbox.

Selection type

The filter can be set up to either include or exclude text. Choose from:

- **1-Including text** where the filter is used to select any zones whose names include the text entered into the **Filter text** below.
- **2-Excluding text** where filter is used to select any zones whose names *do not* include the text entered into the **Filter text** below.

Filter text

Enter the filter text. For example if you wanted to select all zones in the model with the text "corridor" in their zone name then set the Selection type (above) to 1-Including text and enter "corridor" here and press OK. This can be useful as a quick way to load activity, lighting and HVAC templates to particular zone types.

Tip: This tool is much easier to use if zones are named consistently when setting up models.

Match whole zone name only

If the matching should be done on the whole name then check this checkbox. Otherwise the matching will be carried by searching for the filter text anywhere in the zone name.

Filter by tag

If you wish to filter by the zone [tag](#) then check this checkbox.

Selection type

The filter can be set up to either include or exclude text. Choose from:

- **1-Including text** where the filter is used to select any zones whose [tags](#) include the text entered into the **Filter text** below.
- **2-Excluding text** where filter is used to select any zones whose [tags](#) *do not* include the text entered into the **Filter text** below.

Filter text

Enter the filter text. For example if you wanted to select all zones in the model with the text "East" in their zone tag then set the Selection type (above) to **1-Including text** and enter "East" here and press OK. This can be useful as a quick way to load activity, lighting and HVAC templates to particular zone types.

Match whole tag only

If the matching should be done on the whole [tag](#) then check this checkbox. Otherwise the matching will be carried by searching for the filter text anywhere in the tag.

Surfaces

When the **2-Surfaces** selection method is used you can select surfaces based on their orientation and/or slope with an option to limit selection to zones that are already selected on the Load data from template dialog on the Target tab.

Apply orientation range

Check this checkbox if you would like to select surfaces having a particular range of orientations.

Lower orientation limit

Enter the lower end of the orientation range. For example to be sure of selecting all surfaces that are within 5° of south-facing you could enter 175 here and 185 for the upper orientation limit below.

Upper orientation limit

Enter the upper end of the orientation range.

Apply slope range

Check this checkbox if you would like to select surfaces having a particular range of slopes.

Lower slope limit

Enter the lower end of the slope range. For example to be sure of selecting all surfaces that are vertical you could enter 90 here and 90 for the upper slope limit below.

Upper slope limit

Enter the upper end of the slope range.

Filter by tag

If you wish to filter by the surface [tag](#) then check this checkbox.

Selection type

The filter can be set up to either include or exclude text. Choose from:

- **1-Including text** where the filter is used to select any surfaces whose [tags](#) include the text entered into the **Filter text** below.
- **2-Excluding text** where filter is used to select any surfaces whose [tags](#) *do not* include the text entered into the **Filter text** below.

Filter text

Enter the filter text. For example if you wanted to select all surfaces in the model with the text "Curved" in their zone tag then set the Selection type (above) to **1-Including text** and enter "Curved" here and press OK. This can be useful as a quick way to load construction, glazing and/or facade templates to particular surfaces.

Match whole tag only

If the matching should be done on the whole [tag](#) then check this checkbox. Otherwise the matching will be carried by searching for the filter text anywhere in the tag.

Limit selection to currently selected zones only

To ensure that only surfaces in zones that have already been selected on the Load data from templates Target tab are selected check this checkbox.

Openings

When the **3-Openings** selection method is used you can select openings based on their orientation, slope and/or tag with an option to limit selection to zones that are already selected on the Load data from template dialog on the Target tab. Settings work in the same way as for surfaces described above.

Save Data To Template

[Model Data Management](#)

The **Save data to template** tool can be useful to help create a template based on current model settings. For example, if you have set up a particular group of glazing and shading model data selections that you would like to apply to other parts of the model, you can use this tool to create a new [Glazing template](#) using all of the related glazing and shading settings for the current location on the current model data tab. You can then use the [Load data from template](#) tool to apply those settings as required to other parts of the model.

This tool is available from any of the following model data tabs:

- Activity - Activity template,
- Openings - Glazing template
- Lighting - Lighting template
- HVAC - HVAC template

The corresponding template type created is also listed above.

Tip: **Save data to template** can be thought of as the reverse of the [Load data from template](#) process in that data is flowing from the model to a template instead of from the template to the model.

Example

To create a template to quickly apply the settings below made on the Glazing model data tab follow these steps:

Glazing Template	
Template	Project glazing template
External Windows	
Glazing type	Project external glazing
Layout	Preferred height 1.5m, 30% glazed
Dimensions	
Type	3-Preferred height
Window to wall %	30.00
Window height (m)	1.50
Window spacing (m)	5.00
Sill height (m)	0.80
Reveal >>	
Frame and Dividers >>	
Shading	
☒ Window shading	
Type	SageGlass Green
Control type	1-Daylight only
☒ Glare override	
Glare solar beam incident threshold ...	200.0
Glare solar altitude lower threshold (°)	15.0
Glare solar altitude upper threshold (°)	70.0
Operation	
Operation schedule	Office_OpenOff_Occ
☒ Local shading	
Type	0.5m Overhang

1. When you have finished making the model data settings to be saved as a template, click on the **Save data to template** toolbar icon . You could be at building, block, zone, surface or window level for this and the settings of the current object will be saved.

- Open the Save Data to Template dialog, see screenshot below.

Create Template from Model Data - GlazingTemplates

Select the name, category and source for the new template.

Name: SageGlass green with glare control

Category: Project

Source: Project XYZ

Help Cancel OK

- Provide a name for the new template. Enter "SageGlass green with glare control"
- Select the category as "Project"
- Enter some text for the Source, e.g. "Project XYZ".
- When you have finished press OK to close the dialog and create the template.
- Once the template has been created, you are asked whether you would like to select the newly created template for your current object. If you reply yes then, in this example, the new "SageGlass green with glare control" Glazing template will be selected and the Openings model data tab will appear as shown below.

Glazing Template	
Template	SageGlass green with glare control
External Windows	
Glazing type	Project external glazing
Layout	Preferred height 1.5m, 30% glazed
Dimensions	
Type	3-Preferred height
Window to wall %	30.00
Window height (m)	1.50
Window spacing (m)	5.00
Sill height (m)	0.80
Reveal	
Frame and Dividers	
Shading	
☒ Window shading	
Type	SageGlass Green
Control type	1-Daylight only
☒ Glare override	
Glare solar beam incident threshold (W/m2)	200.0
Glare solar altitude lower threshold (°)	15.0

Reload Templates

[Model Data Management](#)

The **Reload templates** option provides a quick way to reload template data for the current building and all its blocks, zones, surfaces and openings. Data is only reloaded if the template selection is non-default. If the template inherits from the hierarchical level above, data is not loaded. This ensures that any model data that was manually overridden reverts back to template settings. After running this command you should not see any model data shown in red bold.

The command opens the [Load data from template](#) dialog with the option **2-Reload templates** selected and all model data tabs selected for updating. You can modify these settings, for example if you only wish to reload data on certain model data tabs.

This option is accessed from the [Edit](#) menu.

Tip: This option can be run after changing template data to ensure that the latest template settings are loaded to the model.

Clear Data To Default

[Model Data Management](#)

The Clear Data to Default dialog allows you to:

- Clear Model Data
- Clear custom openings and revert back to [default facades](#).

The options are:

- **All data** - choose this clear all attributes at the current level
- **All data on current tab** - choose this to clear only the attributes associated with the current model data tab. For example, clear all Constructions data.
- **Currently selected data** (name of currently selected attribute). This option only appears on the dialog when the dialog is opened by right-clicking on a specific attribute. In this case only the selected attributed is cleared.
- **Clear custom openings** - choose to clear any custom openings and revert back to using [default facades](#). This option is only available when the 3-D model is visible.

'Clearing to default' removes any hard-set 'user data' (shown in red) from the current object and instead default data is passed from the 'parent' object in the [hierarchy](#) (Model Data shown in blue).

You can control the extent of the 'clearance' by setting the **Clear Down to** data at the bottom. Leave this data as **Surface level** if you want all data in the currently selected model object (including child objects) to be returned to a default state.

Note: The Clear data to default command does not apply to [CFD boundary](#) object attributes such as window **Flow in** and **Flow out**, Supply diffuser **Flow rate** attribute and all other attributes associated with [CFD boundary objects](#).

See also the [Model data hierarchy and inheritance](#) tutorial

Clear Data to Default used at Building Level

Using **Clear data to default** at building level has a special function. It causes all data below building level in the model hierarchy to be cleared *but does it not clear the data at building level*. This makes sense when you consider that building level is effectively top level as buildings don't inherit any model data from Site level.

The way to understand use of this function at building level is that data at block level and below is cleared which ensures that building data is used throughout the model.

How to Access

The **Clear data to default** dialog can be accessed in 2 main ways:

- From the top toolbar or [Edit menu](#), in which case the clearing can be applied to all data on the current tab or to all data.
- From the context menu when right-clicking on a specific attribute in the model data, in which case only data for the selected attribute is cleared.

Merging Zones

Merging zones is the process whereby zones that are identified as being separate in the model can be merged together with other zones in simulations. This can help to simplify models and speed subsequent calculations.

The Merge Zones dialog can be accessed from the [Tools](#) menu when on the Edit screen. It provides convenient access to the 3 ways of merging zones in DesignBuilder:

1. **Merge zones of same activity** model option.
2. **Merge zones connected by holes** model option.
3. **Selective zone merging**

These zone merging mechanisms are described below. They can also be accessed from the [Model options](#) dialog, though this does not provide the controls for selective merging that are available from the Merge Zones dialog.

Tip: [Selective zone merging](#) is generally the preferred way to merge zones as it gives a greater degree of control over which zone is used as the parent - rather than leaving DesignBuilder to decide based on activity matches or hole connections. This is important because the parent zone's settings are applied to the entire merged group. If a zone with unrepresentative conditions is selected as the parent, the resulting model may no longer represent the building accurately.

More information on merging zones can be found in the [Drawing holes and merging zones](#) tutorial

Merge zones of same activity

This option is a quick and easy way to reduce the number of zones, by merging all zones having the same activity template selection. It should be used with care as it could lead to a very crude zone merging with many zones lumped together.

Merge zones connected by holes

Use this option to merge zones that are connected by [holes drawn at surface level](#) (*not* the holes used to represent the airflow path in [virtual partitions](#)). You can merge one or more zones within the same block or across multiple blocks.

Where holes have been cut in a floor surface to remove it so upper and lower zones can be merged, any small remaining border in the cut floor surface should ideally be removed from the floor area calculation for the combined zone. To do this, you should navigate to the floor surface and tick the option to [Exclude this surface area from the total zone floor area](#) in the Adjacency section of the Construction tab.

Note: when merging 2 or more stacked zones using holes in the floor and the **Merge zones connected by holes option**, you should be aware that the *combined floor area used to calculate internal gains in the simulations will exclude the area of any holes in the floor*. In this case, if you require gains to be calculated using the total upper and lower floor area you should either ensure that the area of the hole is very small or else use the **selective zone merging** option instead and avoid using holes.

Selective Zone Merging

Selective merging controls can be used to merge zones irrespective of their activities or any connection by holes. This is done from Merge Zones dialog (accessed from the [Tools](#) menu) by checking the **Merge zones by selection** checkbox and assigning a parent zone for each zone group and then assigning one or more child zones to the parent to merge them with it. Note that once merged, zones can easily be un-merged again using the [Unmerge](#) button on this dialog.

Once the merge has been applied, the parent zone will control the activity, lighting, HVAC and all other zone-based selections for the entire zone group. Constructions and glazing can still be applied to the child zones.

Any changes made to zone merging settings are only applied when the dialog is closed using the OK button. Closing the dialog with the Cancel button discards any changes.

Creation of the Parent Zone

One zone must be selected to become the parent of the zone group. This zone must not already be either a parent zone or a member of an existing zone group. Selecting a suitable zone in the right hand pane will enable the **Make Parent** button located beneath the right hand pane of the dialog. Clicking this button will create a new entry for the parent zone in the left hand pane (The new zone in the left hand pane will be selected and highlighted).

Merging Zones

With a zone selected in the left hand pane it is now possible to select zones in the right hand pane to become members of the zone group. Zones to be merged cannot already be merged members of an existing group, however the parent of an existing group can be merged. Selecting a valid zone to be merged will enable the **Merge** button located between the two panes of the dialog. Clicking on this button carries out the merge and the newly merged zone will be shown on the tree in the left hand pane. If the parent of an existing zone group is selected and merged then the parent and all of its children become members of the merged zone group.

Unmerging Zones

A single child zone can be removed from a zone group by selecting it in the left hand pane, then using the **Unmerge** button located beneath the pane.

Selecting the parent of a zone group then using the **Unmerge** button will remove all the child zones from the group but will not remove the parent itself. If a parent zone having no children is selected, the text of the unmerge button changes to **Remove Parent**, and the parent zone can be removed from the tree in the left hand pane.

Merging Zones - Discussion

When zones are merged using one of the above methods, combined merged zones are treated as a single zone in thermal calculations. When zones are merged, one of the zones is marked as being the 'parent' zone, and the other zones are 'child' zones. The child zones are marked in blue in the Navigator together with the parent zone they have been merged into as shown below.

The above screenshot of the Navigation list shows the First floor zone, Second floor zone and Roof zones all merged into the Atrium zone.

The parent zone is the zone that is used for defining Activity, HVAC, Lighting (and all other zone related data) for itself and all its child zones. You cannot access this zone-related Model data for merged child zones. You must go to the parent zone to edit the Model data for the combined zone. The internal gains are calculated based on the data set on the Activity tab for the parent zone but using the combined total floor area of all of the merged zones.

Constructions, glazing and other surface level data can be defined separately in each of the parent and child zones in the normal way.

Tip: See also [Zone multiplier](#) for a manual way to reduce models having similar zones and [Boolean operations](#) for how to combine blocks geometrically.

Why merge zones?

You may want to merge zones for various reasons:

- Speed up simulations.
- A geometrically complex space in the actual building is to be modelled using more than one block in DesignBuilder (e.g. [dormer windows](#), atria).
- To reduce the number of zones and simplify HVAC system descriptions when exporting EnergyPlus IDF data for use outside DesignBuilder.
- If you have created a tall merged zone, you may want to use the Air distribution model data on the HVAC tab to create a dynamic vertical temperature gradient. This approach to modelling tall spaces is preferred over connecting a number of horizontal slices with air flow openings, because it does not rely on getting correct airflow conductances between the horizontal slices.

Surfaces between merged zones

When generating data for the calculations, surfaces between zones are defined twice, once from each side. Surfaces between 2 zones that have been merged are called **Surfaces within zone**. By default these are modelled in the same way as standard surfaces but with both sides adjacent to the same zone. If the [Surfaces within zone treated as adiabatic](#) option is set, the 'other side' in each of the 2 surfaces is modelled as adiabatic.

Disadvantages of merging

If done without consideration of the issues, merging zones can reduce cooling load peaks resulting in an underestimate of cooling equipment sizes required to condition the building (and associated energy consumption in a simulation). To understand this, consider a building in the Northern hemisphere with two zones, a North zone and a South zone connected to each other along the E-W axis. When solar gains are highest, the South zone may experience a cooling load and the North Zone not. Now imagine the same 2 spaces merged into a single zone. The combined single zone will now almost certainly have a lower cooling load than the load in the original South zone because the air and surfaces on the South side of the merged space is cooled by the shaded North side.

As simple guide, where the temperatures, internal/solar gains, ventilation, HVAC system and other operational parameters in the actual separate zones are about the same as each other then the merging process should not affect simulation accuracy unduly, however, when merging zones which have different conditions and/or load profiles, the merging will reduce accuracy.

In most cases, merging zones will speed up simulations but occasionally simulations can slow down, especially at the initialisation stage. This may be because any very large zones generated through merging can have many windows which can slow down solar and daylighting initialisation.

Merging rules

1. When merging zones using the [Merge zones of same activity](#) or [Merge zones connected by holes](#), zones connected by the merge option are lumped together into a single 'parent' zone. In a vertical stack of zones the parent will be the lowest zone in the stack.
2. The zone surfaces in merged child zones are generated in exactly the same way as they would have been without the merging but are associated with the parent zone rather than the original child zone.
3. In child merged zones, you can access Constructions and Openings surface-based Model data but not space related data such as Activity, Lighting, HVAC. This is accessed from the parent zone only.

Effect of merging zones on EnergyPlus simulations

EnergyPlus IDF input files are generated without entries for child merged zones (they are not included in the simulation), but their surfaces, windows, doors are included and are associated with the zone description of the parent zone. So in a merged zone model, simulation results are not available for the child zone separately but are available for the overall merged zone. Results for the merged zone can be obtained from the simulation, cooling design and heating design screens either by clicking on the parent zone in the navigator, or by clicking on one of the child zones - the same data for the merged zone is displayed in either case.

Note: For buildings with any zone merging set, heating and cooling design and simulation results are not shown at block level.

Potential problem when merging

One problem users can run into with merged models is related to the Calculated natural ventilation option. For windows placed in zones which are merged child zones where the child zone has the natural ventilation option on the HVAC tab switched off the Operation data on the Openings tab will be hidden. In order to make sure that the natural ventilation is activated for the zone you must temporarily switch off merging, switch on natural ventilation on the HVAC tab for the child zone then switch merging back on again. You should now find that the Operation data is shown.

Merging buildings

You can also 'merge' 2 existing buildings (including component blocks) using the [Transfer blocks](#) command from the Edit menu.

Effect of merging zones on Daylighting simulations

Daylighting simulations ignore the zone merge settings. If it is important for you to combine results for multiple zones for the purposes of daylighting credit calculations you should consider finding another way to combine zones, possibly through the block Union tool to combine blocks or by removing partitions.

Tip: For zones that are stacked one on top of the other with holes in top and bottom to represent slices through an atrium, you can uncheck the [Include zone in daylighting calculations](#) checkbox for the intermediate zones to avoid seeing results for them. Include the lowest zone though so its results are reported.

Zone Level Data For Internal Surfaces

Model data that applies to internal surfaces and openings is generally not available at zone level. This helps to avoid ambiguity in inheritance rules when different settings are made in adjacent zones.

To understand why this is the case, consider a partition between zones A and B. If "partition type 1" is selected as the [Internal partitions](#) model data in zone A, and "partition type 2" is selected in zone B, the inheritance rules indicate that the shared partition could either inherit from zone A ("partition type 1") or from zone B ("partition type 2").

DesignBuilder avoids such ambiguities by preventing Internal partitions from being set at zone level. It does this by hiding the setting when at zone level. Surface level Internal partitions model data settings are instead inherited from block level.

Note that settings for *inter-block* partition surfaces are inherited from the building level for similar reasons.

To summarise:

- Internal surface and opening model data settings are not available for editing at zone level. See below for a full list of the model data settings affected by these rules.
- For internal partitions adjacent to 2 zones in the *same block*, surface level settings are inherited from *block* level.
- For internal partition surfaces adjacent to 2 zones in *different blocks*, surface level settings are inherited from the *building* level.

These rules apply to the following model data settings related to internal surfaces:

Constructions tab

- [Internal partitions](#)
- [Semi-exposed walls](#)
- [Internal sub-surfaces](#)
- [Internal door](#)

Openings tab

- All data under [Internal windows](#) header
- All data under [Doors > Internal](#) header
- All data under [Vents > Internal](#) header

In general, if you need to apply different settings for internal partitions, glazing or any other data listed above in different parts of the model (i.e. you can't just make a building level setting to apply the same change across the whole building), then it may be best to make changes at surface level. In this case the change is automatically applied to the corresponding surface on the other side so there can be no ambiguity.

Tip: If you find that the above rules are slowing down your modelling process because you need to apply multiple different settings to internal surfaces or openings across your model, then you should consider using the [Model data grid tool](#) to speed up the process by making changes to multiple surfaces at once.

The screenshot shows a software interface with a table of surface data and a 'Browse' dialog box.

Table Headers:

- Block
- Zone
- Surface
- Type
- Area (m2)

Load Whole Building Infiltration

The Load Infiltration dialog allows whole building infiltration data obtained from pressurisation tests also referred to as "blower door" tests to be entered and the appropriate infiltration rate is set in model data based on the [infiltration data entry options](#) selected. The whole building infiltration value must be entered in m3/s at 50 Pa pressure difference (even if you have selected [IP units](#)). This flow rate is applied over the whole building and depending on whether the option to "Apportion infiltration to zones based on surface area" is selected, the infiltration flow is either simply set at building level (if the option is unchecked) or is applied differently to each zone depending on the amount of external exposed surface area (if it is checked).

The infiltration flow rates are calculated from the entered whole building value using equations described in EN 12831 including consideration of the exposed area of surfaces in each zone, building height, [wind exposure index](#) and the [infiltration units](#) selected in model options.

Correct Data

When typing a numeric value into a model data text box, if the value is out of range, i.e. it is lower than the minimum value or greater than the maximum value allowed, then the **Correct Data** dialog is displayed. The dialog provides information on the limits as well as ways to fix the error by clearing the value to default or by reloading from the associated template.

Reload

If the data can be loaded from a template then pressing the **Reload** button will reload the data from template to the dialog. If you agree with the change then press the OK button to complete the correction.

Clear

Press the **Clear** button to clear the value to default and close the dialog. The **Clear** button is only enabled when there is a default value to use so for example it is not available when working at building level which is at the top of the model data [hierarchy](#).

Help

Loads this page.

OK

Press the OK button to apply the value in the dialog text box to model data.

Naming Model Objects

Taking an organised approach to naming your model objects can be well worth the effort when it comes to editing and checking models and analysing results. To help with this DesignBuilder allows you to provide a name for most objects in a model. This section provides advice on how to name objects in your model.

Building name

The building name can be edited in the Navigator by clicking on the existing building name to select it and then clicking again to enter edit mode, in the same way that you would rename a file in Windows File Explorer. See screenshot below.

The building name is used as a description alongside the filename on [Simulation Manager](#) lists.

Block name

The block name can be edited in the navigator by clicking on the existing block name to select it and then clicking again to enter edit mode, in the same way that you would rename a file in Windows File Explorer. The block name is used as part of IDF zone names and described below under [EnergyPlus IDF names](#).

Zone name

The zone name can be edited in the navigator by clicking on the existing zone name to select it and then clicking again to enter edit mode, in the same way that you would rename a file in Windows File Explorer. The zone name is used as part of IDF zone names and described below under [EnergyPlus IDF names](#).

Note: The zone name must be unique within the Block to allow IDF names to be generated without extra characters being added by DesignBuilder to ensure uniqueness.

Tip: If you need to rename a lot of zones you can switch on the [Double-click in Navigator to edit model data](#) program option to speed up the process. This can be useful for identifying blocks, zones, surfaces by single-clicking in the Navigator and saves time when renaming many zones at once from block level as it becomes possible to click on the zone Navigator entries to rename them without navigating down to each zone and then having to navigate back up again to block level to rename the next zone.

Surface name

Surfaces are given names automatically by DesignBuilder and these names cannot be changed by users.

Opening name

Openings are given names automatically by DesignBuilder and these names cannot be changed by users.

HVAC components

For Detailed HVAC systems, sub-loop components such as boilers, chillers, pumps, heat exchangers etc have editable names. On the other hand, sub-components such as AHU heating coils, water heater heating elements and all zone components and sub-components have hard-set, non-editable names derived from their parent components.

EnergyPlus IDF Names

DesignBuilder allows you to use a wider set of characters to name objects than are supported by EnergyPlus. This section explains how user-defined names are converted to EnergyPlus IDF names.

Zone names

Any characters in user-defined names not supported by EnergyPlus need to be replaced with characters that are allowed before being used as zone IDF object names. So if you work with intermediate EnergyPlus input or output files and need to be able to easily read IDF object names, or if you write your own [EMS scripts](#), or if

you use the Results Viewer, you should aim to ensure that the block and zone names you enter are such that the none of the steps below cause characters to be removed or replaced.

In summary, zone IDF names are created by adding the parent block name to the zone name itself, separated by the ":" character. For example, "Zone 5" in "Block 1" would be given an IDF zone name of "BLOCK1:ZONE5". The details of the block and zone name process are as described below.

1. The only characters allowed in DesignBuilder-generated IDF zone names are: 0-9, a-z, A-Z. All non-standard characters are replaced by the nearest English equivalent. E.g. "é" would be replaced by "e".
2. Space characters are removed.
3. If no corresponding English equivalent exists then the character is replaced by "X". E.g. "-" would be replaced by "X".
4. Words are capitalised.
5. If the name is greater than 20 characters, all vowels are removed.
6. If the name is still greater than 20 characters, the name is arbitrarily truncated to 20 characters.
7. The block and zones names processed as described above are added together to form a full IDF zone name as block name followed by ":" followed by zone name.
8. The full IDF name is checked for uniqueness and if not unique, an index number is added preceded by the "Q" character. For example if Zone 1 is defined twice in Block 1 then the second zone would be named "BLOCK1:ZONE1Q1" to ensure a difference from the first which would be named "BLOCK1:ZONE1".

Note: Steps 1-6 are applied to both zone and block names individually.

HVAC component names

HVAC component names remain unaltered except in the case where a duplicate name is found in which case an index is added to the end of the name to produce a unique name.

Detailed HVAC

This section describes the graphical interface provided by DesignBuilder for the assembly of component based HVAC systems which may be combined with building models for energy simulation using EnergyPlus.

Overview

HVAC system models in DesignBuilder are assembled by placing a number of pre-defined air and water distribution loops together with groups of zones which are then connected to form complete systems.

See the [Introduction to Detailed HVAC](#) tutorial

In summary, with Detailed HVAC:

- Energy use is calculated based on detailed performance and control parameters such as performance curves, setpoint managers, sequential controls etc.
- Diagrammatic system is built by connecting components of most common type of E+ systems to form loops.
- Air and water distribution systems are modelled using loops for hot water, chilled water loop, condenser and air supply.
- Zone groups are used to specify secondary, zone level system components and zones can have multiple types of terminal units simultaneously.

The [air](#) and [water](#) loops incorporate a number of HVAC components connected together by pipes or ducts to form distribution systems. These loops can be modified to incorporate any additionally required components and then connected to associated components in other loops or to heating, cooling and ventilation equipment located in zones to form complete systems.

Zones are placed in the form of [zone groups](#) which enable a number of zones having the same HVAC equipment to be grouped together. Each zone in the group can have different equipment ratings. The zone group mechanism greatly simplifies the HVAC schematic assembly in that only one set of equipment and connections needs to be defined for the group while maintaining the flexibility of changing equipment properties for individual zones within the group.

The pre-defined loops incorporate [setpoint managers](#) which enable the loop to run without any additional control. However, additional setpoint managers can be added to the various loops to customise the control of the system.

Data associated with all loops, zones and associated [components](#) can be edited via dialogs for specific system requirements.

After placing loops, zone groups and setpoint managers and completing the required loop connections to associated equipment, an EnergyPlus simulation can be conducted for the combined building and HVAC system model.

Accessing Detailed HVAC

To access detailed HVAC, you first need to select the [Detailed HVAC](#) option under the HVAC header on the [Model Options dialog](#). After closing the Model Options dialog, a new **<HVAC System>** node will appear in the Navigator tree list:

Click on this **<HVAC System>** node to access the HVAC edit screen.

Detailed HVAC Terminology

The following points on HVAC terminology may help when referring to the documentation.

- The word "supply air" refers to the air being supplied to the zone. So for example the "supply air flow rate" is the rate of air delivered to the zone. It is not necessarily the *fresh air* delivery rate (though if there is no recirculation then it will be).

HVAC Loops

An HVAC loop is used to model air and water distribution systems such as mechanical ventilation systems, hot and chilled water piped distribution systems and condenser water distribution systems. A loop is divided into two sub-loops, a **demand** sub-loop and a **supply** sub-loop.

See the [Adding loops and connecting components](#) tutorial

At its simplest, a sub-loop comprises an inlet connection (pipe or duct) which is connected in series via a number of components to an outlet connection. The inlet connection of each loop sub-loop connects with the outlet connection of the other loop sub-loop:

The **demand** sub-loop is typically that section of a loop from which energy is **extracted** from a system and the **supply** sub-loop is that section of a loop to which energy is **supplied** by the system.

Consequently, **supply** sub-loops incorporate equipment such as boilers in the case of heating systems or chillers in the case of cooling systems, the supply sub-loop of an air system incorporates items such as heating and cooling coils. The supply sub-loop also contains circulating equipment such as pumps and fans.

Similarly, the **demand** sub-loop of a heating system includes items such as air conditioning heating coils or zone equipment such as hot water radiators, fan-coil unit heating coils, under-floor heating, etc. and similarly a chilled water demand sub-loop contains equipment such as air condition cooling coils, zone cooled beams, chilled ceilings, etc. The sub-loop of an air loop typically incorporates zone air distribution equipment such as VAV boxes, etc.

There are 4 main types of loop:

- **Plant loops** (hot and chilled water loops),
- **Condenser loops,**
- **VRF loops,**
- **Air loops.**

Plant and condenser sub-loops incorporate a flow splitter and a flow mixer which allow a number of parallel branches to be defined. Each parallel branch would normally comprise an inlet connection from the splitter, a component and an outlet connection to the mixer. A by-pass parallel branch (without a component) is also included to ensure flow continuity.

The **supply** sub-loops for **single duct air loops** on the other hand generally comprise a single branch which incorporates an inlet connection connected to various components in series including an outdoor air mixer, fans, cooling coils, heating coils, etc. which are in turn connected to an outlet connection. Air loop supply sub-loops do not contain flow splitters or mixers. **Demand** sub-loops for **single duct air loops** incorporate the supply path connections to zone air distribution equipment and zone return air path connections. Air loop demand sub-loops also incorporate a flow splitter and a flow mixer allowing air distribution equipment in a number of zones to be connected to the supply and return paths:

The outdoor air mixer and fan components in DesignBuilder HVAC are incorporated within an air handling unit component. Optionally, additional components such as heat recovery, heating coils, cooling coils, humidifiers and outdoor air pre-treatment coils can also be added to air handling units:

Air **supply** sub-loops for **dual duct systems** incorporate two outlet connections, one for the hot duct and one for the cold duct; dual duct supply sub-loops also incorporate a single air splitter to split the flow between the hot and cold ducts:

The **demand** sub-loops for **dual duct air loops** similarly contain two inlet connections for hot and cold ducts which can then be connected to zone dual duct air distribution terminals via air splitters and a mixer.

There are various pre-defined loops in DesignBuilder HVAC, 4 [air loops](#), 5 [plant loops](#) a [VRF loop](#) and a [condenser loop](#).

Air Loops

Air loops are used by EnergyPlus to distribute mechanically driven air to zones. In the Air loops provided by DesignBuilder, the air flow supplied into the zones is the same as the flow out. In other words air leakage is not accounted for.

There are 5 pre-defined air loops provided by DesignBuilder detailed HVAC:

- "Air Loop - Generic single duct" on page 712
- "Air Loop - Generic dual duct" on page 712
- "air loop - Unitary heat Cool" on page 713
- "air loop - Unitary heat pump Air to Air" on page 714
- "Air Loop - Unitary Heat Pump Water To Air" on page 714

See the [Adding air loops and AHUs](#) tutorial

Air Loop - Generic Single Duct

This air loop incorporates a [Generic air handling unit \(AHU\)](#) component in the supply sub-loop to which may be added various sub-components including pre-treatment coils (heating and cooling), heat recovery, recirculation with economiser, heating and cooling coils and a humidifier. The air handling unit automatically includes supply and extract fans. The demand sub-loop incorporates a flow splitter and a flow mixer to enable the loop to be connected up to zone equipment. The loop incorporates a single scheduled [setpoint manager](#) which by default is pre-defined to maintain a supply temperature.

See the [Adding air loops and AHUs](#) tutorial

The image below shows a single duct air loop connected to 2 [Zone groups](#).

See also:

- [Air Loop Data](#)

Air Loop - Generic Dual Duct

This air loop is similar to the [Generic single duct air loop](#) but includes two outlet connections for the hot and cold ducts in the supply-sub loop together with associated heating and cooling coils. The loop also incorporates a [Warmest setpoint manager](#) to control the cold duct temperature and a [Coldest setpoint manager](#) to control the hot duct temperature.

The image below shows a dual duct air loop connected to a [Zone group](#).

See also:

- [Air Loop Data](#)

Air Loop - Unitary Heat Cool

The unitary heat cool air loop is similar to the [Generic single duct air loop](#) but instead of a [Generic air handling unit](#), the supply sub-loop contains a [Packaged unitary heat cool AHU](#) component which incorporates [DX heating](#) and [DX cooling coils](#) consequently does not require any plant or condenser loops to be defined.

The image below shows a unitary heat cool air loop connected to a [Zone group](#).

See also:

- [Air Loop Data](#)

Air Loop - Unitary Heat Pump Air To Air

This unitary air loop is similar to the [Generic single duct air loop](#) but instead of a [Generic air handling unit](#), the supply sub-loop contains a [Packaged unitary air to air heat pump](#) component which incorporates [DX heating](#) and [DX cooling coils](#) together with a supplementary electric, hot water or fuel heating coil.

The image below shows a unitary heat pump air to air connected to a [Zone group](#).

See also:

- [Air Loop Data](#)

Air Loop - Unitary Heat Pump Water To Air

This unitary air loop is similar to the [Generic single duct air loop](#) but instead of a [Generic air handling unit](#), the supply sub-loop contains a [Packaged unitary heat pump water to air](#) component which incorporates an On/Off fan component, a WaterToAirHeatPump cooling coil component, a WaterToAirHeatPump heating coil component. The source side (water) of the heat pump is connected to a condenser loop with a heat exchanger (ground heat exchanger or other type) or a plant loop with a heating source such as a boiler and a cooling source such as a chiller or cooling tower.

The image below shows a unitary heat pump water to air connected to a [Zone group](#).

See also:

- [Air Loop Data](#)

Air Loop - Unitary Generic

The Generic Unitary Air Loop consists of a fan component (on/off, constant volume or variable volume), a cooling coil component, a heating coil component, and a reheat coil as shown below. When a draw through configuration is required, the fan is placed directly after the heating coil. If dehumidification control is selected, a reheat coil component is also required. If the reheat coil is present and the dehumidification control type input is not specified as CoolReheat, the reheat coil will not be active.

Note: All of the fan and coil components are optional which allows these loops to be configured for fan-only, heating-only, cooling-only, or both heating and cooling.

The image above shows a unitary generic air loop connected to a [Zone group](#) with heat recovery and recirculation.

- [Air Loop Data](#)

Air Loop - Dedicated Outdoor Air System

The Dedicated Outdoor Air System Air loop (or DOAS loop) is a central air system that delivers outdoor air to one or more child air loop systems. The amount of delivered outdoor air is based on the sum of the outdoor air flow demand from the air loop systems that it serves.

The central DOAS system can pre-treat outdoor air with given precool and preheat air conditions before distributing it to the downstream air loops.

The image above shows a DOAS loop connected to a downstream VAV Air loop.

See also:

- [DOAS Loop Data](#)

Plant And Condenser Loops

A set of pre-defined plant loops are provided:

- [Hot water plant loop](#)
- [Chilled water plant loop](#)
- [Primary/secondary chilled water plant loop](#)
- [Domestic hot water/solar plant loop](#)
- "Solar and Auxiliary Heating Loops" on page 722

A single condenser loop is provided:

- [Condenser loop](#)

A **plant equipment operation** facility is included to provide plant and condenser loops with a mechanism for controlling the operation of the loop and to specify which equipment is available under what conditions. This allows you to model scheduled sequencing of plant equipment depending on time-varying load requirements. For example you may want to model a multiple chiller system and schedule low load chillers to handle loads up to a certain magnitude and then switch in higher load chillers as the cooling load increases. This feature is available through the plant/condenser loop [Plant Equipment Operation](#) tab.

Hot Water Plant Loop

The hot water plant supply sub-loop incorporates a one or more boilers connected in series or parallel, flow splitter and flow mixer together with a circulating pump.

The sub-loop also includes a scheduled temperature [setpoint manager](#) which is set up by default to control the off-plant temperature at a constant 80°C.

The demand sub-loop incorporates a flow splitter and flow mixer in order that the loop can be connected to heating plant components. The image below shows a hot water plant loop connected to 2 [water heating coils](#).

See the [Adding loops and connecting components](#) and [Editing HVAC loop and component properties](#) tutorials

See also:

- "Plant and Condenser Loop Data" on page 733

Chilled Water Plant Loop

The chilled water plant supply sub-loop incorporates one or more chillers connected in either series or parallel, flow splitter and flow mixer together with a circulating pump.

By default, the chiller has a water cooled condenser and connections are included to enable the condenser to be connected up to a condenser loop. Air cooled chillers can also be selected.

The sub-loop also includes a scheduled temperature [setpoint manager](#) which is set up by default to control the off-plant temperature at a constant 6.0°C.

The demand sub-loop incorporates a flow splitter and flow mixer in order that the loop can be connected to cooling plant components. The image below shows a chilled water loop connected to a [water cooling coil](#).

See also:

- "Plant and Condenser Loop Data" on page 733

Primary/Secondary Chilled Water Plant Loop

The primary/secondary chilled water plant loop uses the EnergyPlus Common Pipe Simulation mechanism to represent a chilled water circuit comprising both primary and secondary pumped sub-loops. The primary sub-loop incorporates one or more chillers connected in either series or parallel, flow splitter and flow mixer together with a circulating pump.

By default, the chiller has a water cooled condenser and connections are included to enable the condenser to be connected up to a condenser loop. Air cooled chillers can also be selected.

The primary sub-loop also includes a scheduled temperature [setpoint manager](#) which is set up by default to control the sub-loop outlet temperature at a constant 6°C.

The secondary sub-loop includes a scheduled temperature setpoint manager which is pre-defined to control the sub-loop inlet temperature at a constant 6°C but the schedule defining this temperature can be replaced with any required alternative. The secondary sub-loop also incorporates a flow splitter and flow mixer in order that the loop can be connected to cooling plant components.

Note: In an EnergyPlus common-pipe (primary-secondary) loop the pump must be located on the first (inlet) branch of the half-loop. Branch-level pumps located just ahead of a chiller, as shown by the red arrow in the layout below, are *not* supported.

Domestic Hot Water Plant Loop

The domestic hot water (DHW) plant supply sub-loop incorporates one or more [water heaters](#) connected in series or parallel, flow splitter and flow mixer together with a circulating pump.

The sub-loop also includes a scheduled temperature [setpoint manager](#) which is set up by default to control the off-plant temperature at a constant 55°C.

The demand sub-loop incorporates a flow splitter and flow mixer in order that the loop can be connected to hot water outlets.

The screenshot below shows a typical DHW application with a hot water plant loop connected to DHW loop with a water outlet group.

Another common DHW loop configuration uses an [Air Source Heat Pump](#) on the supply side as shown below:

See also:

- "Plant and Condenser Loop Data" on page 733

Solar And Auxiliary Heating Loops

DesignBuilder enables you to model solar-heated water for domestic hot water (DHW) and/or space heating use. Various configurations of solar heating systems can be created with increasing levels of sophistication using a combination of solar collectors, pumps, water tanks, and water heaters. These include:

- Solar heating system: A simple system where the solar collector is the only heating source linked directly to a DHW loop to supply heated water to zones.
- Solar and Auxiliary heating system: A two-tank system is required to model a solar collector with downstream back-up auxiliary heating which can boost the water temperature if required.
- High-temperature Solar and Auxiliary heating system: Adding a three-way tempering valve enables much higher storage temperatures thereby increasing the capacity of the system to store free solar energy or auxiliary heat purchased during off-peak times.
- Boiler-assisted High-temperature Solar heating system: Boilers can also be connected to serve as the auxiliary heating sources.

These 4 system types are described in more detail below.

Solar Heating System (without auxiliary heating)

A solar heating system can be constructed using the solar loop which comprises a combination of solar collectors, pumps, water tanks and water heaters. [Solar collectors](#) are connected on the demand side of the plant loop. Multiple collector modules can be combined in series and parallel. The supply side of the solar plant loop contains a water heater, circulation pump and setpoint manager to control the loop setpoint. A solar loop can be connected directly to domestic hot water (DHW) loop outlets by first deleting the water heater from the supply side of the [DHW plant loop](#) and then connecting the solar water heater to the DHW supply side splitter and mixer:

Solar and Auxiliary Heating System

To incorporate auxiliary heating it is necessary to model a two-tank system. The storage tank gathers heat directly from the solar collectors and stores it for later use. The auxiliary water heater is positioned downstream of the storage tank on the supply side of the DHW plant loop. The auxiliary water heater, or booster water heater, provides additional heat if the storage tank water is not hot enough. The auxiliary water heater can be modelled as an instantaneous/tankless water heater or as a standard tanked water heater with heating source (see [Water Heater component](#)):

High-temperature Solar and Auxiliary Heating System

Another strategy to consider for solar heating systems is to allow the storage tank to reach a much higher temperature than necessary for the end use. This allows the tank to store more energy from the solar collectors, when it is available. However, for applications such as domestic hot water, it is undesirable and unsafe to supply excessive hot water temperatures at the point of demand. To take advantage of higher storage temperatures, yet still avoid scalding temperatures at the tap, the hot water leaving the storage tank can be tempered with cold water using a three-way valve ([tempering valve](#)) to achieve the target temperature. An additional auxiliary DHW heating loop is provided by DesignBuilder HVAC which incorporates this arrangement. A solar loop water heater can be directly connected to the supply side splitter and mixer of an auxiliary heating loop:

Boiler-assisted High-temperature Solar Heating System

Another common solar hot water loop arrangement similar to above but this time with auxiliary heating from a hot water loop with [boiler](#):

This arrangement of components and loops models a typical solar heating system with 2 tanks: a solar tank with water at potentially high temperatures and an auxiliary tank containing water at temperatures that can be used by heating and/or DHW purposes. The **Solar Assisted DHW** HVAC template provides this functionality.

More information on how to configure and control Solar and Auxiliary heating loops can be found on the [Solar Hot Water](#) help page.

Why is the solar collector on the *demand* side of the loop?

The demand is the loop demand rather than a component demand, i.e. the demand is created by the need to satisfy the setpoint on the solar loop supply sub-loop outlet. In other words, the more the outlet temperature from the water heater element drops below the setpoint, the higher the demand on the collectors.

See also:

- "Solar Loop Data" on page 738

Condenser Loop

The condenser supply sub-loop incorporates one or more [cooling towers](#) connected in series or parallel, flow splitter and flow mixer together with a circulating pump. The default sub-loop also includes a scheduled temperature [setpoint manager](#) which is pre-defined to control the off-plant temperature at a constant 29°C.

The demand sub-loop incorporates a flow splitter and flow mixer in order that the loop can be connected to condenser components such as a [water cooled chiller](#).

The graph below (reproduced with permission from CIBSE) illustrates the vapour compression cycle. The condenser process takes the fluid from saturated vapour (point 5) to saturated liquid (point 6) on the graph below.

CIBSE Guide B Figures 4.8 and 4.9

See the [Condenser loops cooling tower](#) tutorial

See also:

- "Plant and Condenser Loop Data" on page 733

VRF Loops

A VRF system is an air-conditioning system that varies the refrigerant flow rate using variable speed compressor(s) in the outdoor unit, and the electronic expansion valves (EEVs) located in each indoor unit. The system meets the space cooling or heating load requirements by maintaining the zone air temperature at the setpoint. The ability to control the refrigerant mass flow rate according to the cooling and/or heating load enables the use of as many as 60 or more indoor units with differing capacities in conjunction with one single outdoor unit. This unlocks the possibility of having individualized comfort control, simultaneous heating and cooling in different zones, and heat recovery from one zone to another. It may also lead to more efficient operations during part-load conditions.

There are two alternative VRF models in EnergyPlus:

- The system provided in DesignBuilder is the system curve based model (VRF-SysCurve). In this model, a number of system level curves are used to describe the VRF system performance. This model corresponds to the AirConditioner:VariableRefrigerantFlow object.
- Physics based model (VRF-FluidTCtrl) has been recently introduced into EnergyPlus. It is able to consider the dynamics of more operational parameters and is applicable for fluid temperature control. This model corresponds to the AirConditioner:VariableRefrigerantFlow:FluidTemperatureControl object.

Refer to the [Engineering reference](#) for more technical details of the two models.

VRF indoor units are placed within HVAC zones like other [zone forced air units](#). They include pre-configured direct-expansion cooling and/or heating coils.

VRF loops are not like other loops in DesignBuilder HVAC as they consist simply of a single [VRF outdoor unit](#) connected to one or more [VRF indoor units](#) through a dotted line.

There is no data associated with the VRF loop itself - it mainly serves as a container for the VRF outdoor unit and the connections to the indoor units.

Loop Data

There are 3 plant and air loop dialogs:

- "Air Loop Data" on page 729
- Editing DOAS Air Loop
- "Plant and Condenser Loop Data" on page 733
- "Solar Loop Data" on page 738

Air Loop Data

The air loop edit dialog allows you to control the way that the air system is sized and in particular in how the design supply and outside air flow rates as well as heating and cooling capacities are calculated.

See the [Adding air loops and AHUs](#) and [Editing Generic air loop and system components](#) tutorials

General

Name

This is the name of the loop. If the supplied loop name is found to already exist, the software will automatically append an integer to create a unique name.

Design return air flow fraction of supply air flow

This setting specifies the design air loop return air flow rate as a fraction of the supply flow rate when there is no exhaust flow. It can be used to set zero return air flow for a DOAS system or to model a pressurized system where the return flow is a fraction of the supply flow. The return air flow rate will never be greater than the current supply air flow rate multiplied by this fraction. It may be less if there is unbalanced exhaust from any zones served by this air loop. The default is 1.0, the minimum allowed value is 0 and the maximum is 1.

Sizing

The rest of the Air loop dialog provides the sizing inputs needed to perform a central forced air system design air flow, heating capacity, and cooling capacity calculation for a system serving one or more zones. The information needed consists of the outside environmental conditions and the design supply air temperatures, outdoor air flow rate, and minimum system air flow ratio.

The outside conditions come from the design days in the input. A **system sizing** calculation is performed for the design day defined in the input file and the resulting maximum heating and cooling air flow rates and capacities are used in the **component sizing** calculations.

Supply air conditions are specified by inputting a supply air temperature for cooling, a supply air temperature for heating, and a preheat temperature. The system sizing calculation sums the zone design air flow rates to obtain a system supply air flow rate. The design conditions and the outdoor air flow rate are used to calculate a design mixed air temperature. The temperature plus the design supply air temperatures allows the calculation of system design heating and cooling capacities.

Note: Detailed HVAC [autosizing calculations](#) are not to be confused with [Heating](#) and [Cooling design](#) calculations, which use separate simpler data entry from the [HVAC tab](#). No Detailed HVAC data is used for Heating and Cooling design calculations, which are based on the EnergyPlus Ideal loads system.

Design outdoor air flow rate

The design outdoor air flow rate (in m³/s or ft³/min). Generally this should be the minimum outdoor air flow. It is used for both heating and cooling design calculations. The assumption for cooling is that any outdoor air economizer will be closed. If **Autosize** is input the Design outdoor air flow rate used in the simulations will be taken from the sum of the zone outdoor air flow rates based on the [Sizing option](#) below.

Note that the Design supply air flow rate is defined in the AHU dialog contained within the Air loop.

Central heating maximum system air flow ratio

This ratio is used in calculating the central system heating capacity and is only required when the [Fan type](#) of the attached AHU is **2-Variable volume**. It should be set so as to define the expected system flow rate when maximum heating demand occurs. Thus if the system is VAV with the zone VAV dampers held at minimum flow when there is a zone heating demand, this ratio should be set to the minimum flow ratio. If the zone VAV dampers are reverse action and can open to full flow to meet heating demand, this ratio should be set to 1.

The value entered must be between 0 and 1.

Sizing option

The Sizing option is set to as follows:

- **1-Non-coincident** where the central system air flow rate will be sized on the sum of the non-coincident zone air flow rates. This option is normally used for CAV systems.
- **2-Coincident** where the central system air flow rate will be sized on the sum of the coincident zone air flow rates. This option is normally used for VAV systems,

Type of load to size on

For CAV air loops you can define the way the central system supply air flow rate is sized. The choices are:

- **1-Sensible** means that the central system supply air flow rate will be determined by combining the zone design air flow rates, which have been calculated to meet the zone *sensible* loads from the design days. In addition this option tells the program to size the central cooling coil using entering air flow rate and air conditions at the sensible load peak.
- **2-Ventilation requirement** means that the central system supply air flow rate will be determined by the system ventilation requirement.
- **3-Total** means that the central system supply air flow rate will be determined by combining the zone design air flow rates, which have been calculated to meet the zone *total sensible + latent* loads from the design days. In addition this option indicates that the program should size the central cooling coil at the air flow rate and conditions at the total load peak.

The central heating coil is always sized at the conditions at the peak sensible heating load.

For VAV systems you should select either **1-Sensible** or **3-Total**.

Important Note: For CAV air loops used to model a dedicated outdoor air system (DOAS), you must set the **Type of load to size on** to **2-Ventilation requirement**. This is true even if the air is being pre-heated and/or pre-cooled to temper it before delivery.

System outdoor air method

The method used to calculate the system minimum outdoor air flow. The two choices are:

- **1-Zone sum** which sums the outdoor air flows across all zones served by the system.
- **2-Standard 62.1 ventilation rate procedure** (VRP) which uses the multi-zone equations defined in 62.1 to calculate the system outdoor air flow. VRP may also adjust autosized air terminal maximum and minimum supply flow rates if needed to ensure adequate outdoor air flow rate to each zone. VRP considers zone air distribution effectiveness and zone diversification of outdoor air fractions.
- **3-Standard 62.1 simplified procedure** (SP) is similar to VRP and was introduced in ASHRAE Standard 62.1-2019. The main difference compared to VRP is that it uses a simplified approach to calculate a system's ventilation efficiency which is in turn used to calculate the system outdoor air flow. Additionally, when set to autosize, the minimum (primary) air flow (or air flow fraction) of these types of air terminals will be calculated following SP: "Variable Air Volume with No Reheat ADU" on page 1123 (Constant minimum Air flow fraction or Fixed minimum air flow fraction), "Variable Air Volume with Reheat ADU" on page 1118 (Constant minimum air flow fraction or Fixed minimum air flow fraction), "Series Powered Induction Unit with Reheat ADU" on page 1125 (Minimum primary air flow fraction), "Parallel Powered Induction Unit with Reheat ADU" on page 1126 (Minimum primary air flow fraction).

Note: When the **Type of load to size on** is set to **2-Ventilation requirement** the **System outdoor air method** control is set to **1-Zone sum** and the control is greyed out.

Zone maximum outdoor air fraction

For an air loop, when a zone requires outdoor air higher than the user specified **Zone maximum outdoor air fraction**, the zone supply air flow will be capped at the maximum value. This allows the system level outdoor air flow to be reduced while the total supply air flow increases. Valid values are from 0 to 1.0. Default is 1.0 which indicates zones can have 100% outdoor air maintaining backward compatibility. This inputs work for constant volume air systems, single and dual duct VAV systems.

Heating

Preheat design temperature

This is the design air temperature exiting the preheat coil (°C or °F).

Preheat design humidity ratio

This is the design humidity ratio exiting the preheat coil (in kg/kg).

Central heating design supply air temperature

This is the design supply air temperature for heating (°C or °F). It can be either the reset temperature for a single duct system or the actual hot duct supply air temperature for dual duct systems. It should be the temperature at the exit of the main heating coil.

The default value for newly added air loops is 16°C corresponding to a reheat-type system where the zone temperature control is provided through local reheat terminal units.

Note: For a centralised system where the AHU is to provide zone heating, you should increase this value to say 35-50°C in order for the heating coil sizing to be performed correctly.

100% Outdoor air in heating

This data is set as follows:

- **1-No** for systems with recirculation set in the AHU, the system will be sized for heating using minimum outside air.
- **2-Yes** for systems without recirculation set in the AHU, the system will be sized for heating using 100% outdoor air.

Central heating design supply air humidity ratio

This is the design humidity ratio at the exit of the central heating coil (in kg/kg) . The default is 0.008.

Heating design air flow method

The input must be either:

- **1-Design day** which means the program will calculate the system design heating air flow rate using the System Sizing input data and a design day simulation.
- **2-Flow/System** which means that the program will use the input of the field [Heating Design Air Flow Rate](#) as the system design heating air flow rate.

The default method is **1-Design day**, i.e., the program uses the calculated design values.

Heating design air flow rate

This is the design system heating air flow rate (m³/s or ft³/min). This input is an alternative to using the program calculated value. This input is used if [Heating design air flow method](#) is **2-Flow/System**. This value will not be multiplied by any sizing factor or by zone multipliers. If using zone multipliers, this value must be large enough to serve the multiplied zones.

Cooling

Pre-cool design temperature

This is the design air temperature exiting the pre-cooling coil (°C or °F).

Pre-cool design humidity ratio

This is the design humidity ratio exiting the pre-cooling coil (kg/kg).

Central cooling design supply air temperature

This is the design supply air temperature for cooling (in °C or °F). This should be the temperature of the air exiting the central cooling coil.

This value should typically be lower than the [Central heating design supply air temperature](#).

100% Outdoor air in cooling

This data is set as follows:

- **1-No** for systems with recirculation set in the AHU, the system will be sized for cooling using minimum outside air
- **2-Yes** for systems without recirculation set in the AHU, the system will be sized for cooling using 100% outdoor air.

Central cooling design supply air humidity ratio

This is the design humidity ratio at the exit of the central cooling coil (in kg/kg). The default is 0.008.

Cooling design air flow method

The input must be either:

- **1-Design Day** which means that EnergyPlus will calculate the system design cooling air flow rate using the System Sizing input data and a design day simulation.
- **2-Flow/System** where the [Cooling design air flow rate](#) below is used as the system design cooling air flow rate.

The default method is **1-Design Day**, i.e. the program uses the calculated design values.

Cooling design air flow rate

This is the design system cooling air flow rate (m³/s or ft³/min). This input is an alternative to using the program calculated value. This input is used if [Cooling design air flow method](#) is **2-Flow/System**. This value will not be multiplied by any sizing factor or by zone multipliers. If using zone multipliers, this value must be large enough to serve the multiplied zones.

Availability schedule

Schedule values greater than zero (usually 1 is used) indicate that the system is on. Schedule values less than or equal to zero (usually 0 is used) denote that the system is off. This schedule overrides the air loop fan schedules for determining whether the fans are on.

DOAS Loop Data

The DOAS loop edit dialog allows you to configure the preconditioning settings for the DOAS system.

General

Name

This is the name of the DOAS loop. If the supplied loop name is found to already exist, the software will automatically append an integer to create a unique name.

Heating

Preheat design temperature

The design air temperature exiting the preheat coil (if any) (in °C or °F).

Preheat design humidity ratio

The design humidity ratio exiting the preheat coil (if any) (in kgWater/kgDryAir or lbWater/lbDryAir).

Cooling

Precool design temperature

The design air temperature exiting the precool coil (if any) (in °C or °F).

Precool design humidity ratio

The design humidity ratio exiting the precool coil (if any) (in kgWater/kgDryAir or lbWater/lbDryAir).

Plant And Condenser Loop Data

The plant and condenser loop edit dialog incorporates two tabs, the first tab is General and incorporates loop characteristic and sizing data, the second tab covers [Plant Equipment Operation](#) allowing you to set up various equipment operation schemes for the loop.

See the [Adding loops and connecting components](#), [Editing HVAC loop and component properties](#) and the [Condenser loops cooling tower](#) tutorials

General

Name

If the supplied loop name is found to already exist, the software will automatically append an integer to create a unique name.

Fluid type

You can define the type of fluid used in the loop as a mixture of water and glycol along with the particular concentration being used. EnergyPlus will accurately model the thermal properties of the fluid based on glycol concentration and fluid temperature at each time step of the simulation.

Select the fluid type from 3 options:

- **1-Water.**
- **2-EthyleneGlycol.**
- **3-PropyleneGlycol.**

Glycol concentration

When one of the glycol fluid types is selected above then you can enter the concentration of glycol in the loop fluid here. It should be entered as a decimal fraction between 0.0 and 1.0. A concentration of 0.0 refers to pure water. A concentration of 1.0 would denote 100% of the fluid referenced in the Fluid type input above.

Plant loop volume

This is the volume of the plant loop (in m³ or gal). This is the loop volume for the entire loop, i.e. both the demand side and the supply side. This is used for the loop capacitance calculation which updates the loop temperature from one time-step to the next and introduces some time delay between the supply and demand sides of the loop. The loop volume could be calculated from pipe size data but this is not usually known. If zero volume is specified the demand inlet temperature is set to the supply outlet temperature at the previous system time-step. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. If the loop volume is auto-calculated, the EnergyPlus provided calculation gives reasonable values for most system sizes. This calculation is described in the [EnergyPlus Engineering Reference](#) manual.

Flow Type

Plant loop flow type

Two options are available:

- **1-Constant flow**, for constant flow plant loops. In this case a [constant speed pump](#) will automatically be specified.
- **2-Variable flow** for variable flow plant loops. In this case a [variable speed pump](#) will automatically be specified.

The flow type is fixed as **1-Constant flow** for DHW and condenser loops

Temperatures

Maximum loop temperature

This is the maximum allowable temperature (in °C or °F) for this loop.

Minimum loop temperature

This is the minimum allowable temperature (in °C or °F) for this loop.

Flow Rates

Maximum loop flow rate

This is the maximum loop flow rate (in m3/sec or ft3/min). This parameter is also used when the user chooses to auto-calculate the loop volume. See the [Plant loop volume](#) above and the [EnergyPlus Engineering Manual](#) for more details.

Note: This value is generally autosizable but only when the condenser loop does not contain any Vertical ground heat exchanger components. In cases where a vertical ground heat exchanger is included the **Maximum loop flow rate** should normally take the same value as entered on the ground heat exchanger dialog for [Maximum flow rate](#) and [Design flow rate](#). The Condenser loop **Maximum loop flow rate** can be entered as higher than the ground heat exchanger flow rate but in this case it will be limited to that value during the simulation.

Minimum loop flow rate

This is the minimum loop flow rate (in m3/sec or ft3/min).

Load distribution scheme

The Load distribution scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, 3 schemes are functional:

- **1-Sequential** uses each piece of equipment to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand.
- **2-Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand.
- **3-Uniform** evenly distributes the loop demand amongst all available components on the equipment list for a given load range.

Plant loop demand calculation scheme

The **Plant loop demand calculation scheme** determines the amount of heating or cooling necessary to bring the temperature of the Plant loop to its setpoint. When this value is determined then the **Load distribution scheme** explained in the previous section takes this value and distributes the load to the appropriate equipment. The demand calculation scheme determines how the load is calculated. See more information in the EnergyPlus Engineering Document. There are 2 plant loop demand calculation schemes:

- **1-SingleSetPoint** scheme in which the Plant loop requires that a [Setpoint manager](#) sets a single setpoint value. Examples of this setpoint manager are [1-Scheduled](#), SetpointManager:OutsideAir etc.
- **2-DualSetPoint** scheme in which the Plant loop requires that a [17-Dual setpoint](#) SPM sets the high and low setpoint values for heating and cooling to implement a mixed water loop.

Sizing

Design loop exit temperature

The water temperature (in °C or °F) at the exit of the supply side of the plant loop, Thus this is the temperature of the water supplied to the inlet of chilled or hot water coils in the case of plant loops or chiller condensers in the case of condenser loops.

Loop design temperature difference

This is the design temperature rise (for cooling or condenser loops) or fall (for heating loops) (in °C or °F) across the demand side of a plant or condenser loop.

Operation

Availability schedule

This is the [schedule](#) that determines whether or not the Plant loop is available during the simulation. A schedule value greater than 0 (usually 1 is used) indicates that the device can be on for the timestep. A value less than or equal to 0 (usually 0 is used) denotes that the device must be off.

Outside temperature operation

If you select this option you can define the external temperatures below and above which, the plant or condenser loop will turn off as a deadband. The definition is different depending on the type of plant loop as shown below.

Loop type	External cut-in temperature	External cut-out temperature
Hot water plant loops	The temperature (in °C or °F) below which the plant is on.	The temperature (in °C or °F) above which the plant is forced off.
Chilled water and condenser plant loops	The temperature (in °C or °F) is the temperature above which the plant is on.	The temperature(in °C or °F) below which the plant is forced off.

Note: When either of the cut-in or cut-out conditions occurs they override the availability schedule. For example in the case of a hot water loop, when the **Outside temperature operation** check box is selected, if the outside air dry-bulb temperature is below the **External cut-in temperature** then the loop is cycled on (it is available) or if it is above the **External cut-out** temperature then the loop availability is forced off (not available), otherwise the loop availability is controlled by the **Availability schedule** alone.

Plant Equipment Operation

Plant and condenser loops have a mechanism for controlling the operation of the loop to allow control over which equipment is available under what conditions. Since there may be multiple control schemes that are assigned various priorities associated with each loop, an overall operation scheme must be defined. Each operation scheme must have the type of operation scheme together with the name of the scheme and the schedule that defines its availability.

Note: The order in which the individual operation schemes appear in this list defines its priority relative to the others with the same scheduled availability. The first scheme appearing in the list is given the highest priority; the second scheme has second highest priority, etc. In other words, if according to its schedule, the first operation scheme is available, then it is used by the simulation to define how the plant or condenser loop operates. If it is not available, the second operation scheme in the list is checked to see if it is available until the highest priority scheme that is also available is found. To allow for simultaneous heating and cooling, there is one configuration where multiple operation schemes are available at a given timestep. This

is allowed if a user inputs both a heating range based operation and a cooling range based operation with overlapping schedules. The simulation will look at the current loop demand to determine if the cooling scheme should be used or the heating scheme. In other cases, if two schemes overlap (are available at the same time), EnergyPlus will raise an error and the simulation will be aborted.

Number of schemes

This is the number of operational schemes that are to be associated with the plant or condenser loop. A maximum of ten schemes are allowed for each loop. After setting the required number of schemes, the dialog will be automatically populated with sections for each scheme, the settings for each operation scheme being described below.

Scheme

Scheme operation type

This is the type of control scheme used. The available options will depend on the current loop type. For condenser and chilled water plant loops, the options are:

- **1-Uncontrolled** and
- **2-Cooling load**

for heating and domestic hot water plant loops, the options are:

- **1-Uncontrolled** and
- **3-Heating load**.

for chilled water loops with [Ice thermal storage](#) components included, 2 further Scheme operation types are allowed:

- **4-Component Setpoint**, for use only with Ice thermal storage systems, this option requires various setpoint managers, temperature schedules, etc. to allow the system to operate. As complex definitions are possible for this scheme, it allows the possibility of more accurate and flexible modelling, for instance, setting hourly variation of setpoint temperatures at the outlet of each piece of equipment. The screenshot in the [Controls and Chilled Water Plant Loop Operation Scheme Settings](#) section of the Ice thermal storage help topic shows how to use Setpoint managers to control an upstream chiller with ice thermal storage series configuration with the scheme operation type set to **4-Component Setpoint**.
- **5-Energy Thermal Storage**, for use only with Ice thermal storage systems, this scheme operation type internally creates the setpoint managers required by the equipment and so allows a simple and convenient approach by eliminating the need for both setpoint manager and schedule for each piece of equipment. The only data required is a charging setpoint temperature and a discharging setpoint temperature. The screenshot in the [Controls and Chilled Water Plant Loop Operation Scheme Settings](#) section of the Ice thermal storage help topic shows how to control a downstream chiller with ice thermal storage series configuration with the scheme operation type set to **5-Energy Thermal Storage**.

Uncontrolled loop operation simply specifies a group of equipment that runs 'uncontrolled'. If the loop runs, this equipment will run also, unless turned off by the loop flow resolver to maintain continuity in the fluid loop.

The **2-Cooling load** and **3-Heating load** options allow different load ranges to be defined and which items of equipment will operate for each range. If either of these options is selected, at least one operational range must be defined. For each range, there is a lower limit for the load range, an upper limit for the load range, and a list of the equipment items that will operate in this range.

Scheme equipment

This setting is only displayed if the [Scheme operation type](#) is set to **1-Uncontrolled**. A list of valid items of plant or condenser equipment is displayed together with check boxes allowing you to define which items of equipment will be turned on for this scheme.

Scheme schedule

This is the schedule for the control scheme. This schedule consists of weeks and days, with the days containing "0 or 1" for each hour of the day. This binary schedule (0 for off, 1 for on) determines if the control scheme is operating for that hour of the day or not.

Number of ranges

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load** and is used to define the number of ranges required for the heating or cooling load scheme.

Range

Range lower limit

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load**. This is the lower demand range (W) for the equipment defined for the current range. If demand is below this value, then the equipment will not turn on to meet the demand.

Range upper limit

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load**. This is the upper demand range (W) for the equipment defined for the current range. If demand is above this value, then the equipment will not turn on to meet the demand.

Range Equipment

A list of valid items of plant or condenser equipment is displayed together with check boxes allowing you to define which items of equipment will be turned on for this range. This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load**.

Note: A priority drop-list associated with each item of equipment allows you to define the order in which equipment will be turned on when the loop demand is within this range.

Solar Loop Data

The Solar loop edit dialog incorporates two tabs, the first tab is General and incorporates loop characteristic and sizing data, the second tab covers [Plant Equipment Operation](#) allowing you to set up various equipment operation schemes for the loop.

General

Name

If the supplied loop name is found to already exist, the software will automatically append an integer to create a unique name.

Fluid type

There is currently only one fluid type available which is **1-Water**.

Plant loop volume

This is the volume of the plant loop (in m³ or gal). This is the loop volume for the entire loop, i.e. both the demand side and the supply side. This is used for the loop capacitance calculation which updates the loop temperature from one time-step to the next and introduces some time delay between the supply and demand

sides of the loop. The loop volume could be calculated from pipe size data but this is not usually known. If zero volume is specified the demand inlet temperature is set to the supply outlet temperature at the previous system time-step. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. If the loop volume is auto-calculated, the EnergyPlus provided calculation gives reasonable values for most system sizes. This calculation is described in the [EnergyPlus Engineering Reference](#) manual.

Flow Type

Plant loop flow type

Two options are available:

- **1-Constant flow**, for constant flow plant loops. In this case a [constant speed pump](#) will automatically be specified.
- **2-Variable flow** for variable flow plant loops. In this case a [variable speed pump](#) will automatically be specified.

Temperatures

Maximum loop temperature

This is the maximum allowable temperature (in °C or °F) for this loop.

Minimum loop temperature

This is the minimum allowable temperature (in °C or °F) for this loop.

Flow Rates

Maximum loop flow rate

This is the maximum loop flow rate (in m³/sec or ft³/min). This parameter is also used when the user chooses to auto-calculate the loop volume. See the [Plant loop volume](#) above and the [EnergyPlus Engineering Manual](#) for more details.

This value is autosizable.

Minimum loop flow rate

This is the minimum loop flow rate (in m³/sec or ft³/min).

Load distribution scheme

The Load distribution scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, 3 schemes are functional:

- **1-Sequential** uses each piece of equipment to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand.
- **2-Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand.
- **3-Uniform** evenly distributes the loop demand amongst all available components on the equipment list for a given load range.

Plant loop demand calculation scheme

There is currently only one plant loop demand calculation scheme which is the **1-SingleSetPoint** scheme. In this scheme the Plant loop requires that a [Setpoint manager](#) set a single setpoint value. The **Plant loop demand calculation scheme** determines the amount of heating or cooling necessary to bring the

temperature of the Plant loop to its setpoint. When this value is determined then the [Load distribution scheme](#) explained in the previous section takes this value and distributes the load to the appropriate equipment. The demand calculation scheme determines how the load is calculated. See more information in the EnergyPlus Engineering Document.

Temperature Protection

Low temperature protection

Check this option to apply low temperature protection for the loop. The system will turn on if the temperature at the solar collector water outlet node is below the trigger temperature input defined below.

Temperature below which system is on

Set the temperature below which the system must switch on to protect the loop from damage caused by low temperatures such as freezing. Units are °C or °F. The default value is 0°C.

High temperature protection

Check this option to apply high temperature protection for the loop. The system will turn off if the temperature at the loop water heater DHW outlet node is above the temperature input defined below.

Temperature above which system is off

Set the temperature above which the system must switch off to protect the loop from damage caused by high temperatures. Units are °C or °F. The default value is 90°C.

Differential Thermostat

The aim of the differential thermostat settings is to prevent the water heater from being supplied with inadequately heated water by the solar collector. These settings allow an availability manager to be provided to switch the loop on or off depending on the temperature differential between a collector outlet and the outlet from the water heater. A [differential sensor check box](#) on the solar collector dialog allows you to define the collector to be used by the differential sensor (in cases where there is more than one solar collector on the loop).

Note: only one solar collector on the loop can have its [Differential thermostat hot node sensor](#) checkbox checked.

Differential thermostat

Check this option to use a differential thermostat on the [Solar HW loop](#).

Temperature difference to turn system on

The temperature (in Delta°C or Delta°F) above which the loop can operate.

Temperature difference to turn system off

The temperature (in Delta°C or Delta°F) below which the loop will be shut off.

Sizing

Design loop exit temperature

The water temperature (in °C or °F) at the exit of the supply side of the plant loop, Thus this is the temperature of the water supplied to the inlet of chilled or hot water coils in the case of plant loops or chiller condensers in the case of condenser loops.

Loop design temperature difference

This is the design temperature rise (for cooling or condenser loops) or fall (for heating loops) (in °C or °F) across the demand side of a plant or condenser loop.

Operation

Availability schedule

This is the [schedule](#) that determines whether or not the Plant loop is available during the simulation. A schedule value greater than 0 (usually 1 is used) indicates that the device can be on for the timestep. A value less than or equal to 0 (usually 0 is used) denotes that the device must be off.

Plant Equipment Operation

Plants and condenser loops have a mechanism for controlling the operation of the loop to allow control over which equipment is available under what conditions. Since there may be multiple control schemes that are assigned various priorities associated with each loop, an overall operation scheme must be defined. Each operation scheme must have the type of operation scheme together with the name of the scheme and the schedule that defines its availability.

Note: The order in which the individual operation schemes appear in this list defines its priority relative to the others with the same scheduled availability. The first scheme appearing in the list is given the highest priority; the second scheme has second highest priority, etc. In other words, if according to its schedule, the first operation scheme is available, then it is used by the simulation to define how the plant or condenser loop operates. If it is not available, the second operation scheme in the list is checked to see if it is available until the highest priority scheme that is also available is found. To allow for simultaneous heating and cooling, there is one configuration where multiple operation schemes are available at a given timestep. This is allowed if a user inputs both a heating range based operation and a cooling range based operation with overlapping schedules. The simulation will look at the current loop demand to determine if the cooling scheme should be used or the heating scheme. In other cases, if two schemes overlap (are available at the same time), EnergyPlus will raise an error and the simulation will be aborted.

Number of schemes

This is the number of operational schemes that are to be associated with the plant or condenser loop. A maximum of ten schemes are allowed for each loop. After setting the required number of schemes, the dialog will be automatically populated with sections for each scheme, the settings for each operation scheme being described below.

Scheme

Scheme operation type

This is the type of control scheme used. The available options will depend on the current loop type. For condenser and chilled water plant loops, the options are:

- **1-Uncontrolled** and
- **2-Cooling load**

for heating and domestic hot water plant loops, the options are:

- **1-Uncontrolled** and
- **3-Heating load**.

Uncontrolled loop operation simply specifies a group of equipment that runs 'uncontrolled'. If the loop runs, this equipment will run also, unless turned off by the loop flow resolver to maintain continuity in the fluid loop.

The **2-Cooling load** and **3-Heating load** options allow different load ranges to be defined and which items of equipment will operate for each range. If either of these options is selected, at least one operational range must be defined. For each range, there is a lower limit for the load range, an upper limit for the load range, and a list of the equipment items that will operate in this range.

Scheme equipment

This setting is only displayed if the [Scheme operation type](#) is set to **1-Uncontrolled**. A list of valid items of plant or condenser equipment is displayed together with check boxes allowing you to define which items of equipment will be turned on for this scheme.

Scheme schedule

This is the schedule for the control scheme. This schedule consists of weeks and days, with the days containing "0 or 1" for each hour of the day. This binary schedule (0 for off, 1 for on) determines if the control scheme is operating for that hour of the day or not.

Number of ranges

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load** and is used to define the number of ranges required for the heating or cooling load scheme.

Range

Range lower limit

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load**. This is the lower demand range (W) for the equipment defined for the current range. If demand is below this value, then the equipment will not turn on to meet the demand.

Range upper limit

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load**. This is the upper demand range (W) for the equipment defined for the current range. If demand is above this value, then the equipment will not turn on to meet the demand.

Range Equipment

This setting is only displayed if the Scheme Operation Type is set to **2-Cooling load** or **3-Heating load**. A list of valid items of plant or condenser equipment is displayed together with check boxes allowing you to define which items of equipment will be turned on for this range.

Note: A priority drop-list associated with each item of equipment allows you to define the order in which equipment will be turned on when the loop demand is within this range.

HVAC Zones And Zone Groups

HVAC zone groups are used to simplify HVAC layouts by grouping together zones that have identical configurations of HVAC equipment but not necessarily the same equipment ratings. Consequently, only a

single set of equipment items needs to be added to the group and only one set of connections between air/plant loops and zone group equipment need to be established.

See the [HVAC zone groups and components](#) tutorial

As an example, consider a building model where five ground floor zones are to be cooled and ventilated using a VAV box without reheat supplied by a single AHU and the zones are to be heated using radiators supplied by the same heating circuit. A single zone group can be used to incorporate the equipment for the five zones within the HVAC layout.

From HVAC System level, a zone group can be [placed](#) and then [edited](#) to include the ground floor zones:

After adding the zones, the zone group becomes active and you can navigate down to it, either by double-clicking on the graphic in the Edit screen or by selecting it from the navigator. At the zone group level, you can see all of the zones added to the group:

You can then navigate down to any one of the zones to add the required equipment:

Now when you move back up to the zone group level, you will notice that the zone equipment has automatically been added to all zones in the group:

You can now navigate down to equipment in any zone to change the equipment default settings:

At the system level, only one set of connections is required to connect the equipment in all of the constituent zones up to the air and plant loops:

When data is written to the EnergyPlus IDF file prior to simulation, all constituent zones, zone equipment and zone equipment connections are written out separately.

See also:

[Edit HVAC zone data.](#)

HVAC Component Hierarchy And Navigation

HVAC systems are structured using a similar hierarchical system to that used by the DesignBuilder building model:

Methods of navigating the HVAC system are the similar to those used for navigating the building model (see [Navigating Building Models](#) for further information). To move down to an object lower down in the hierarchy, you can either select the object graphically on the Edit screen and double-click on it or alternatively, just select it from the navigator tree list at the left of the screen. To move up a level, you can either press the F2 key, or select the required level object from the Navigator.

After moving down to an object, only that object and any related components in other objects will be active, all other objects in the hierarchy will become inactive and displayed in grey on the Edit screen.

Note: DesignBuilder HVAC does not use the same [hierarchical data inheritance](#) system as the building model. In particular [HVAC zone groups](#) are used to define default data for newly added [HVAC zones](#) but their data is not inherited down to its HVAC zones.

HVAC System Control - Setpoint Managers

The [setpoint manager](#) is the main mechanism through which the behaviour of HVAC system loops is controlled. All HVAC loops require at least one setpoint manager to specify the supply sub-loop outlet temperature and these are automatically included in all pre-defined HVAC loops. Setpoint managers will place a calculated or scheduled setpoint value at the point or connection in the loop at which the setpoint manager control line has been placed. No two setpoint managers should be located on the same connection for like control types otherwise an error message will be displayed and the simulation aborted.

There 15 different types of setpoint manager available. However only certain types of setpoint manager are available for different types of air loops and plant/condenser loops:

- [1-Scheduled](#) (All loops).
- [2-Warmest](#) ([Generic](#) and [dual duct](#) air loops only).
- [3-Coldest](#) ([Generic](#) and [dual duct](#) air loops only).
- [4-Multi-zone minimum humidity average](#) (Air loops only).
- [5-Multi-zone maximum humidity average](#) (Air loops only).
- [6-Multi-zone humidity minimum](#) (Air loops only).
- [7-Multi-zone humidity maximum](#) (Air loops only).
- [8-Single zone humidity minimum](#) (Air loops only).
- [9-Single zone humidity maximum](#) (Air loops only).
- [10-Outdoor air reset](#) (Generic and dual duct air loops, plant and condenser loops).
- [11-Single zone heating](#) (Air loops only).
- [12-Single zone cooling](#) (Air loops only).
- [13-Multi-zone cooling average](#) (Air loops only).
- [14- Multi-zone heating average](#) (Air loops only).
- [15-Follow ground temperature](#) (Condenser loops only)

Refer to the [Setpoint manager](#) section for information regarding specific setpoint manager types.

Setpoint Manager Used With Draw-Through Fans

Adjusting setpoints for fan pickup

When placing Setpoint managers on a node *upstream of a draw-through fan* you may need to manually adjust the setpoint to take into account the temperature rise that will take place as the air flows across the fan.

Mixed air Setpoint Managers

The Mixed Air Setpoint Manager is a special type of setpoint manager which is automatically added to air handling units that incorporate coils located before the supply fan and where no setpoint manager has been added explicitly before the fan. This type of setpoint manager works in conjunction with the AHU outdoor air controller (see Air Handling Unit Outdoor Air System). The Mixed Air Setpoint Manager is used to establish a temperature setpoint at the mixed air node. The AHU outdoor air controller then operates the outdoor air damper to attempt to meet this setpoint. The main function of the Mixed Air Setpoint Manager is to pick up a temperature setpoint provided by a setpoint manager located downstream of the supply fan and then set this value as the off-coil setpoint, having first subtracted the calculated temperature rise across the supply fan.

Note: A Mixed Air Setpoint manager is only included in systems that incorporate 'draw-through' coils. Also, if a setpoint manager is added in front of a draw-through fan, the Mixed Air Setpoint manager is omitted.

Working At HVAC System Level

The HVAC system level is at the top of the hierarchy of the building HVAC data. At HVAC system level, you can:

1. Use the [Load HVAC template](#) dialog to load a fully connected HVAC system. When there are no HVAC loops or HVAC zone groups defined already and you navigate to the HVAC system level, this dialog is opened automatically.
2. Use the [Save HVAC Template](#) tool to save the currently defined system as a template for future use.
3. [Add](#) and edit [air, plant and condenser loops](#).
4. [Add](#) and [edit zone groups](#).
5. Delete one or more existing HVAC components. Either select the component(s) for deletion and use the **Delete** toolbar icon or, to delete all components, use the Delete tool with no components selected.

Load HVAC Template Dialog

You can use the Load HVAC Template dialog to load a fully connected HVAC system to the model either in addition to any system data already defined or to replace it. To load an HVAC template, first go to the [HVAC System level](#) then click on the **Load HVAC Template** tool.

Note: You can find a summary description of all the available HVAC templates in the [HVAC Templates Overview](#) Guide.

Note: When there are no HVAC loops or HVAC zone groups defined already and you navigate to the HVAC system level, this dialog is opened automatically.

Select The HVAC System Template

The first page on the **Load HVAC Template** dialog allows you to select the predefined HVAC system you would like to load. The thumbnail image shows an image of the system layout currently selected.

To select a different HVAC system, click on the Detailed HVAC template browse item to reveal the browse button and click on the browse button to bring up a list of available templates. With this list open simply select the HVAC system you would like and press the OK button.

Once you have the right HVAC system selected click on the Next button in the **Load HVAC Template** dialog.

Select Building Zones

On the second page you can select the building zones to be served by the selected HVAC template. By default all zones that are currently not already served are selected. You will normally want to unselect any unoccupied zones or other zones that are not served by this system.

Load HVAC template

VAV Reheat, Water-cooled Chiller, Full Humidity Control: Select the zones served by this HVAC System

Use the check boxes to select the zones to be served by this HVAC system.

Zones

- ☒ Training Building

 - ☒ Open Office N
 - ☒ Open Office S
 - ☒ Open Office W
 - ☒ Roof
 - ☐ Roof Void

Options

- ☒ Replace all existing HVAC systems
- ☒ Override template defaults

Cancel Help Back Next Finish

Replace all existing HVAC systems

On this page of the dialog you can choose to **Replace all existing HVAC systems** which, as the name suggests, removes any existing HVAC components before placing the selected HVAC system and allows all zones in the building to be selected as being served by the selected HVAC template.

Override template defaults

This option allows you to override the default settings saved with the template using your own values on further pages on this dialog.

Air System Data

If the HVAC template includes an air system and you chose to override template defaults then on this page you get the opportunity to provide key settings for the air system.

Load HVAC template

Chiller	
 Chiller template	DOE-2 Centrifugal/5.50COP

Loading The Template

When you have entered all of the necessary data click on the Finish button. If there is no existing HVAC data or you chose to replace all existing HVAC data then the components associated with the template are placed automatically on the HVAC layout screen. Alternatively, if the HVAC template is being used to add components to an existing system, you should use the mouse to position the new components away from the existing ones and click with the mouse to actually place them. You may need to zoom out to find a free area to place the new components.

Tip: See the [Save HVAC Template](#) page for specific guidance on [loading custom HVAC templates](#)

Note: If you click on an area where the new HVAC components would overlap with any that already exist then the load is cancelled.

See the [Introduction to Detailed HVAC](#) tutorial

Save HVAC Template

Use the **Save HVAC Template** tool if you would like to save the HVAC system defined in your model for loading to this or other models in the future.

Summary - how to save a custom HVAC template

To save a custom HVAC template, follow these steps:

1. Go to the [HVAC System level](#) by click on the **<HVAC System>** item in the Navigator.
2. Open the [Save HVAC Template dialog](#) by clicking on the **Save HVAC Template** icon on the toolbar.
3. On the dialog, enter a descriptive name for your template.
4. Press the OK button to save the template.

Save HVAC Template dialog

The Save HVAC Template dialog allows you to name the HVAC template and provides a summary of the sub-systems that will included with the saved template.

When you press the OK button to save the template the HVAC data is stored in the template library.

Note: The whole HVAC system, as seen at HVAC system level, is saved and there is no way to selectively save particular parts of the system.

Loading custom HVAC templates

Any HVAC systems saved as a template will be available for subsequent loading using the [Load HVAC Template](#) dialog. The HVAC template library is global to the program and so any HVAC templates that you save will automatically be available in other projects on your machine.

To load your custom HVAC template:

1. Go to the [HVAC System level](#) by click on the **<HVAC System>** item in the Navigator.
2. Load the template by clicking the **Load HVAC Template** icon to launch the [Load HVAC Template](#) dialog.
3. Select your custom template by clicking the ellipsis (...) to the right of the **Detailed HVAC Template** control and navigate to your template in the **User** folder.
4. Select the zones to include in the first zone group of this template. See note below.
5. Click the Finish button to load the system.

Note: When loading custom templates saved from more complex HVAC layouts with more than 1 zone group, only the first zone group in the system can be populated with zones from the [Load HVAC Template](#) dialog. However, you can easily assign zones to the other zone groups from the [HVAC zone group](#) dialog as required after the template has been loaded .

Exporting custom HVAC template(s)

You can [export](#) your HVAC template library in DDF form just like any other type of template or component. This is the most secure method to store your HVAC templates as the DDF file can be loaded to other machines and in future installations.

Managing custom HVAC templates

To manage your custom Detailed HVAC templates, follow these steps:

1. Ensure DesignBuilder is in [non-learning mode](#). In this case all templates are listed under the **Templates** tab on the Navigator.
2. Open the **Detailed HVAC Templates** list item and then open the **User** category item below that to display the list of custom HVAC templates
3. Use the icons at the top of the Navigator panel to delete or view custom templates in the list.
4. To rename a template, click on the template in the list, then click again to open the list label editor, and type in the new name.

See the [Introduction to Detailed HVAC](#) tutorial

Add Zone Group Tool

To place an [HVAC zone group](#), first go to the [HVAC System level](#) and click on the Add zone group tool. To place a zone group, simply move the cursor to the required position on the Edit screen and click the mouse button to place the zone group.

See the [HVAC zone groups and components](#) tutorial

Add Loop Tool

To place an HVAC loop, first go to the HVAC System level and click on the Add loop tool which will display a drop-menu of available pre-defined loops. You can then select the type of loop you require from the menu.

Having selected the loop type, to place it, move the cursor to the required position on the Edit screen and click the mouse button.

See the [Adding loops and connecting components](#) tutorial

Auto Connect Tool

This tool can be used to boost your productivity when connecting HVAC plant loops to equipment in Zone groups and Air loops. To connect one or more Plant loops to one or more HVAC loops and Zone groups:

1. Navigate to HVAC System level.
2. Select all loops and Zone groups to be connected. Use <Ctrl> + mouse click or the rubber band selection tool to select more than one object.
3. Click on the [Connect components](#) toolbar icon to automatically make the connections.

The diagram below illustrates the process.

Not yet connected → Select Loops and Zone Groups Together → Connected with a single click

The animation below shows a specific example.

With a **single click**, DesignBuilder created 32 pipe connections across eight additional AHUs

Tip: The initial positioning of loops and zone groups can significantly affect the layout of connections generated. The Auto connect tool doesn't try to avoid line intersections, so sometimes the connection layout won't look quite as you would draw it yourself. However if you're not happy with the result you can always undo the connection, reposition the objects and try again.

Note: There are some limitations in what can be automatically connected to what. For example chilled water loops or hot water loops won't be automatically connected to heat pump condensers. Any connections that were not made automatically can be completed manually using the [Connect components](#) tool in the usual way.

See also: "Connect Components Tool" on page 769

Working At Sub-Loop Level

At the sub-loop level, you can:

1. [Add](#) and [Edit](#) Boilers (heating plant supply sub-loop)
2. [Add](#) and [Edit](#) Chillers (chilled water plant supply sub-loop)
3. [Add](#) and [Edit](#) Cooling towers (condenser supply sub-loop)
4. [Add](#) and [Edit](#) Water heaters (domestic hot water plant supply sub-loop)
5. [Add](#) and [Edit](#) Pumps (all plant and condenser supply sub-loops)
6. [Add](#) and [Edit](#) Heating coils (dual-duct air loop supply sub-loop)
7. [Add](#) and [Edit](#) Cooling coils (dual-duct air loop supply sub-loop)
8. [Add](#) and [Edit](#) Humidifiers (dual-duct air loop supply sub-loop)
9. [Add](#) and [Edit](#) Water heater heat pumps.
10. [Add](#) and [Edit](#) Setpoint managers (all supply sub-loops)
11. [Add](#) Mixers and Splitters (all sub-loops)
12. [Connect components](#) (all sub-loops)
13. [Edit air handling units](#) (air loop supply sub-loop)

Note: Sub loops have no attribute data of their own so there is no sub-loop dialog.

Add Boiler Tool

[Boilers](#) can only be incorporated within the supply sub-loops of hot water plant loops so you first need to go to the supply sub-loop of the hot water plant loop to which the boiler is to be added. The Add boiler tool icon will then appear on the toolbar. To place a boiler, click on the Add boiler tool and then move the mouse cursor to the required position and click the mouse button to place the boiler.

Add Chiller Tool

[Chillers](#) can only be incorporated within the supply sub-loops of chilled water plant loops so you first need to go to the supply sub-loop of the chilled water plant loop to which the chiller is to be added. The Add chiller tool icon will then appear on the toolbar. To place a chiller, click on the Add chiller tool and then move the mouse cursor to the required position and click the mouse button to place the chiller.

Add Cooling Tower Tool

[Cooling towers](#) can only be incorporated within the supply sub-loops of condenser loops so you first need to go to the supply sub-loop of the condenser loop to which the cooling tower is to be added. The Add Cooling Tower tool icon will then appear on the toolbar. To place a cooling tower, click on the Add Cooling Tower tool and then move the mouse cursor to the required position and click the mouse button to place the cooling tower.

Add Water Heater Tool

[Water heaters](#) can only be incorporated within the supply sub-loops of domestic hot water plant loops so you first need to go to the supply sub-loop of the domestic hot water plant loop to which the water heater is to be added. The Add Water Heater tool icon will then appear on the toolbar. To place a water heater, click on the Add Water Heater tool and then move the mouse cursor to the required position and click the mouse button to place the water heater.

Add Pump Tool

Pumps can only be included in the supply sub-loops of plant and condenser loops. EnergyPlus requires that the pump must be the first component in the sub-loop. Consequently, a pump must be connected directly to the sub-loop inlet node. Only one pump can be added to each plant/condenser supply sub-loop and so the tool will only appear on the toolbar at the plant/condenser sub-loop level if you delete the existing pump in order to change its orientation.

To place a pump, click on the Add pump tool and click the mouse button when the pump is at the required location. After clicking the mouse button, you can then rotate the pump by moving the mouse in a circular direction around the centre of the pump to obtain the required orientation:

Add Heating Coil Tool

Heating coils can only be incorporated within the supply sub-loops of air loops so you first need to go to the supply sub-loop of the air loop to which the coil is to be added. The Add heating coil tool icon will then appear on the toolbar. To place a heating coil, click on the Add heating coil tool.

Heating coils can be placed anywhere in the sub-loop but are more commonly incorporated within an air handling unit. To add a heating coil to an air handling unit, after clicking on the Add heating coil tool, move the cursor (with the coil attached to it) into the supply section of the air handling unit and click the mouse button to place the coil at the required location. Coils may be placed in front of the supply fan for a 'draw-through' configuration or after the fan for a 'blow-through' configuration:

Add Cooling Coil Tool

Cooling coils can only be incorporated within the supply sub-loops of air loops so you first need to go to the supply sub-loop of the air loop to which the coil is to be added. The Add cooling coil tool icon will then appear on the toolbar. To place a cooling coil, click on the Add cooling coil tool and then select the required coil from the drop-list.

Cooling coils can be placed anywhere in the sub-loop but are more commonly incorporated within an air handling unit. To add a cooling coil to an air handling unit, after clicking on the Add cooling coil tool, move the cursor (with the coil attached to it) into the supply section of the air handling unit and click the mouse button to place the coil at the required location. Coils may be placed in front of the supply fan for a 'draw-through' configuration or after the fan for a 'blow-through' configuration:

Add Humidifier Tool

Humidifiers can only be incorporated within the supply sub-loops of air loops so you first need to go to the supply sub-loop of the air loop to which the humidifier is to be added. The Add humidifier tool icon will then appear on the toolbar. To place a humidifier, click on the Add humidifier tool.

Humidifiers can be placed anywhere in the sub-loop but are more commonly incorporated within an air handling unit. To add a humidifier to an air handling unit, after clicking on the Add humidifier tool, move the cursor (with the humidifier attached to it) into the supply section of the air handling unit and click the mouse button to place the humidifier at the required location. Humidifiers may be placed in front of the supply fan for a 'draw-through' configuration or after the fan for a 'blow-through' configuration:

Add Splitter/Add Mixer Tool

Splitter and mixers are used in HVAC in order to connect multiple items of equipment to a sub-loop by means of parallel branches:

Note: Only one splitter and one mixer can be incorporated within both the supply and demand sub-loops of plant and condenser loops and consequently the Add splitter and Add mixer tool will only appear on the toolbar if an existing splitter and mixer have been removed.

Air loops are slightly different in that air supply sub-loops comprise series component connections and consequently do not require any splitter or mixer with the exception of dual-duct systems which incorporate a single splitter to enable the flow to be split between hot and cold ducts. Air demand sub-loops are similar to plant and condenser sub-loops in that they can only contain a single mixer but can incorporate an additional splitter to cater for dual duct systems.

To place a splitter or mixer, click on the Add splitter or Add mixer tool and click the mouse button when the splitter/mixer is at the required location. After clicking the mouse button, you can then rotate the splitter/mixer by moving the mouse in a circular direction around the centre of the component to obtain the required orientation:

Add Supply/Return Plenum Tool

Plenums may be used to model building features such as ceiling or floor voids which are used to supply or return centrally conditioned air. Supply and return plenums are essentially uncontrolled building zones incorporated within the supply and return paths of air loop demand side sub-loops. Plenums can account for building side heat balance, that is they can transfer heat with other zones through surfaces, but they cannot incorporate HVAC equipment.

HVAC air plenums are special types of component since there is a heat balance connection and building description and a system airflow connection that transfers the airflow directly from a supply plenum to a controlled zone or from a controlled zone to a return plenum in the system air simulation.

Placing plenums

When an air loop is first placed, a splitter and mixer component is automatically included on the supply and return sides respectively. The normal way to place a supply plenum is to first delete the original splitter component and replace it with a supply plenum component. Likewise to include a return plenum, first delete the original mixer component and replace it with a return plenum component.

To place a supply or return plenum, click on the **Add supply plenum** or **Add return plenum** tool and click the mouse button when the plenum is at the required location. After clicking the mouse button, you can then rotate the plenum to its final orientation by moving the mouse in a circular direction around the centre of the component:

Connecting plenums

When you first place a plenum it will be shown on the HVAC layout diagram in light grey indicating that it does not yet have a building zone allocated to it and so cannot yet be connected up. So the first thing to do having placed a supply or return plenum is to [assign a building zone to the Plenum component](#).

Finished system with supply and return plenums

Note: Each air loop demand sub-loop can contain a single return plenum but can incorporate an additional supply plenum to cater for dual duct systems.

Add Water Heater Heat Pump

[Water heater heat pumps](#) (aka Air to Water Heat Pumps or ASHPs) are normally placed on the Supply side of DHW and Auxiliary loops. To do this, navigate to the Supply side of the DHW or Auxiliary loop, click on the **Add Water Heater Heat Pump** tool and left click with the mouse to place it.

In the example below, a Water heater heat pump is placed on the Supply side of a DHW loop. On the Demand side of that loop, water is supplied to a Water heater and to a Hot water radiator within an HVAC zone.

Note: Water heater heat pumps can also be added at the HVAC zone level, in which case, they are referred to as "Zone water heater heat pumps". See: [Add Zone Water Heater Heat Pump](#)

Add Setpoint Manager

Setpoint Managers are one of the high-level control constructs in EnergyPlus. A Setpoint Manager (SPM) is able to access data from any of the HVAC system nodes and use this data to calculate a setpoint (often a temperature setpoint) for one or more other HVAC system nodes.

Setpoint managers are added from the sub-loop level by clicking on the **Add Setpoint manager** toolbar icon. The process is summarised below,

1. Navigate to the sub-loop where the SPM is to be added.
2. Click on the **Add Setpoint manager** toolbar icon to start the command.
3. Move the mouse cursor to the sensor point on the sub loop layout schematic, i.e. to the point where the SPM will sense the conditions as in input to the control logic. A red marker appears on the line at this point.
4. Click with the mouse to define the sensor point. A "tentative" SPM schematic object now appears on the screen, moving as you move the mouse cursor.
5. Move the mouse to point on the diagram where you would like the SPM itself to be placed and click with the mouse to place it.

6. Select the SPM so it is highlighted in red and right click on it with the mouse to open the context menu. Now click on the **Edit** menu item to open the [Edit Setpoint Manager](#) dialog. Here you can enter the SPM details such as type, control variable etc.

Connect Components Tool

The **Connect components** tool is used to create connections between the inlets and outlets of both air-side and water-side components. The tool can only be used at the sub-loop level. HVAC connections are created in the form of a number of segments or steps, each segment snapped to the X or Y axis. To create a connection between two components, first click on the Connect components tool and move the cursor to the required component inlet/outlet. When the cursor is over the required inlet/outlet, a green connection marker will be displayed to indicate that the beginning of the connection can be snapped to the inlet/outlet:

You can then click the mouse button to start the connection. Having snapped the beginning of the first connection segment to the required inlet/outlet, as you move the mouse cursor away, the cursor will automatically snap to the X or Y axis depending on the position of the cursor relative to the connection point. As you move the cursor across the screen, drawing guides are displayed to indicate that the current cursor position has been automatically snapped to align with existing connections in the X and Y axes:

When the cursor snaps to a required drawing guide, you can then click the mouse button to place the end point of the current connection segment. Finally, as you move the cursor towards the component inlet/outlet to which the connection is to be created, a green connection marker will again be displayed to indicate that the end of the connection can be snapped into position by clicking the mouse cursor button.

See also "Auto Connect Tool" on page 759.

See the [Adding loops and connecting components](#) tutorial

Working At HVAC Zone Group Level

When at the HVAC zone group level, you can edit the current zone group if no HVAC zones are selected by clicking on the Edit icon in the toolbar. Alternatively you can edit HVAC Zone data by selecting the HVAC zone in the Edit screen - it will be highlighted in red. Then right-click and in the menu select the Edit option.

- [Edit HVAC zone data.](#)

Working At HVAC Zone Level

When at the HVAC zone level, if no zone components are selected, you can edit the current HVAC zone by clicking on the Edit icon in the toolbar. Also, at the HVAC zone level, you can:

1. [Add](#) and [Edit](#) Air distribution units (VAV boxes, Chilled beams etc.).
2. [Add](#) and [Edit](#) Forced air units (Fan-coil units, etc.).
3. [Add](#) and [Edit](#) Radiant surfaces.
4. [Add](#) and [Edit](#) Heated floors.
5. [Add](#) and [Edit](#) Chilled ceilings.
6. [Add](#) and [Edit](#) Radiators/convectors.
7. [Add](#) and [Edit](#) High temperature radiant heaters.
8. [Add](#) and [Edit](#) Water heater heat pumps.
9. [Add](#) a Zone extract.
10. [Add](#) and [edit](#) Zone exhaust fan.

See also:

"Editing HVAC Zone Data" on page 928

Add Zone Air Distribution Unit Tool

[Zone air distribution units](#) are placed at the HVAC zone level. To place an ADU, navigate to the HVAC zone, click on the **Add air distribution unit** tool and then select the required unit from the drop-list. Then, making sure that the cursor is inside the boundary of the zone, left click with the mouse to place the ADU. The ADU will be automatically positioned at the top left of the zone:

You should make sure to add a distribution unit that is compatible with the type of air loop you plan to connect to. The constant volume ADUs available in DesignBuilder can connect to both CAV and VAV air loops, while Variable volume ADUs can only connect to VAV air loops.

Note You must also add a zone [extract unit](#) to a zone that contains an ADU in order to connect up the air return path from the zone.

Add Zone Forced Air Unit Tool

[Forced air units](#) are placed at the HVAC zone level. To place a forced air unit, navigate to the HVAC zone, click on the **Add forced air unit** tool and then select the required unit from the drop-list. Then, making sure that the cursor is inside the boundary of the required zone, left click with the mouse to place the unit. The unit will be automatically positioned at the bottom left of the zone:

Add Zone Radiant Surface Tool

[Radiant Surfaces](#) are placed at the HVAC zone level. To place a Radiant Surface, navigate to the HVAC zone, click on the **Add Radiant Surface** tool and then, making sure that the cursor is inside the boundary of the required zone, left click with the mouse to place it.

The Radiant Surface will be automatically positioned at the bottom of the zone:

Add Zone Heated Floor Tool

[Heated floors](#) are placed at the HVAC zone level. To place a heated floor, navigate to the HVAC zone, click on the **Add heated floor** tool and then, making sure that the cursor is inside the boundary of the required zone, left click with the mouse to place the heated floor.

The heated floor will be automatically positioned at the bottom of the zone:

Add Zone Chilled Ceiling Tool

[Chilled ceilings](#) are placed at the HVAC zone level. To place a chilled ceiling, navigate to the HVAC zone, click on the **Add chilled ceiling** tool and then, making sure that the cursor is inside the boundary of the required zone, left click with the mouse to place the chilled ceiling.

The chilled ceiling will be automatically positioned at the top of the zone:

Note: Where chilled ceilings are added to zones with internal ceilings, the floor surface of the associated adjacent upper zone must have a construction with an internal source to represent the embedded piping system of the chilled ceiling. Similarly, in the case of zones with external flat roofs, the roof construction must contain an internal source. Refer to the documentation on [Constructions](#) for further information on defining [internal sources](#) for constructions.

Add Zone Radiative-Convective Unit Tool

[Radiators and convectors](#) are placed at the HVAC zone level. To place a radiator or convector, navigate to the HVAC zone, click on the **Add radiative-convective unit** tool and then select the required unit from the drop-list. Then, making sure that the cursor is inside the boundary of the required zone, left click with the mouse to place the radiator/convector.

The unit will be automatically positioned at the bottom centre of the zone:

Add Zone High Temperature Radiant Heating

[High temperature radiant heaters](#) are placed at the HVAC zone level. To place a High temperature radiant heater, navigate to the HVAC zone, click on the **Add High temperature radiant heating** tool and then, making sure that the cursor is inside the boundary of the required zone, left click with the mouse to place it.

The High temperature radiant heating component will be automatically positioned at the top of the zone:

Add Zone Water Heater Heat Pump

[Zone water heater heat pumps](#) (aka Air to Water Heat Pumps or ASHPs) are placed directly in an HVAC zone. In this case, you must also connect it to an Auxiliary heating or DHW loop.

The application below represents a Water heater heat pump located inside a zone and connected to a DHW loop. An example of this application is an apartment building or hotel where the heat pump water heater is installed in a plant or utility room. The unit draws heat from the air in that room and uses it to heat the domestic hot water, so its operation can cool the room and affect the zone heat balance. In the model, the ASHP is therefore placed in the HVAC zone to represent this air-side interaction, while its water side is connected to the DHW loop supplying the building's hot-water outlets.

Note: In this case, the Zone Water Heater Heat Pump must be connected to a *single zone* HVAC group. You should create a separate HVAC Group for each zone that includes a Zone Water Heater Heat Pump. Placing the zone water heat pump in the HVAC zone without connecting it to an Auxiliary heating or DHW loop is not allowed.

Note: Water heater heat pumps can also be added on the Supply side of a DHW or Auxiliary loop. See: [Add Water Heater Heat Pump](#)

Add Zone Extract Tool

Zone extracts are placed at the HVAC zone level and are used to return air back to the AHU. To place an extract, navigate to the HVAC zone, click on the **Add zone extract tool**. Then, making sure that the cursor is inside the boundary of the zone, left click with the mouse to place the extract.

The extract unit will be automatically positioned near the top right of the zone:

Note: A zone extract is required in an [HVAC Zone](#) if an [ADU](#) has been placed.

The Zone extract does not require any data to be entered and so does not appear on the Navigator list. It is not to be confused with the [Zone exhaust fan](#) which is used to extract air direct to outside and can be linked to the Airflow Network.

Add Zone Exhaust Fan Tool

Zone exhaust are placed at the HVAC zone level and are used to extract air to outside. To place an extract, navigate to the HVAC zone, click on the **Add zone exhaust fan** tool and then making sure that the cursor is inside the boundary of the zone just click the mouse button to place the extract.

The exhaust fan will be automatically positioned at the top right of the HVAC zone:

Note: A zone exhaust fan can be added in addition an extract in an [HVAC Zone](#) if an [ADU](#) has been placed. Alternatively it can included without an ADU and extract.

Data for the zone exhaust fan data can be entered on the [Zone exhaust fan](#) dialog. It is not to be confused with the Zone extract which is used to return air back to the AHU.

Working At HVAC Component Level

Many components in DesignBuilder HVAC are composite components and are themselves composed of a number of sub-components. Examples of composite components include air handling units and various items of zone equipment such as forced air units (fan-coil units, etc.) and air distribution units (VAV terminal boxes with reheat, etc.). In order to access and edit the data associated with each sub-component of a composite component you first need to go to the component level (by selecting it from the navigator or double-clicking on it with the mouse) and then you can select and edit any of the appropriate sub-components:

Autosizing HVAC Components

In many cases, HVAC component sizes can be autosized by EnergyPlus. All settings that can be autosized are displayed in dark blue on the component edit dialogs. The special keyword **Autosize** must be typed into the edit control on the component edit dialog if a setting is to be autosized.

For example, for a [hot water coil](#), the Maximum water flow rate can be autosized:

Autosizing In EnergyPlus

EnergyPlus is able to automatically size many HVAC components based on user-specified building configuration and design external conditions.

By default DesignBuilder automatically provides data on 2 sizing periods, one for winter, the other for summer for sizing heating and cooling equipment respectively. If [multiple summer design months](#) have been selected these will all be used in the summer simulation cooling autosizing as well. EnergyPlus uses this design day weather data to specify outside conditions when autosizing HVAC components.

Information on how zone load sizing is to be carried out can be entered for each zone (on the [HVAC zone dialog](#)). Also data governing how air loops are to be sized can be entered for each air system on the [Air loop dialog](#). Likewise sizing data for plant and condenser loops is entered on [Plant loop dialogs](#).

Other than zone thermostat setpoints, the sizing calculations generally know nothing about the system control inputs defined on [Setpoint managers](#) and availability schedules. You must coordinate the sizing inputs on the HVAC zone and air loop dialogs with the actual simulation control inputs.

The sizing calculations only recognize the presence of central heating and cooling coils, preheat and precool coils and reheat coils. These are assumed to deliver the various supply temperatures specified in the [Air loop](#) and [HVAC Zone](#) objects. The impact of their sub-components such as heat recovery, dehumidifiers, fans, and pumps are not accounted for in the sizing calculations.

Note: The Detailed HVAC autosizing calculations referred to on this page are not to be confused with [Heating](#) and [Cooling design](#) calculations which use separate simpler data entry from the [HVAC tab](#). **No Detailed HVAC data is used for Heating and Cooling design calculations**, which are based on the EnergyPlus Ideal loads system.

Schedules and Sizing

Close attention should be paid to [Schedules](#). When using [7/12 schedules](#) you must make sure that the appropriate [Design day definition](#) is made to ensure that they reflect appropriate summer and winter design days respectively. Likewise [Compact schedules](#) provide the **SummerDesignDay** and **WinterDesignDay** day types and these must be set up correctly.

Some commonly used applications of summer and winter design days in schedules are:

1. Setting internal loads (lights, equipment, occupancy) to maximum all day for cooling and to zero all day for heating;
2. Setting heating and cooling thermostat set points to constant values (no set up or set back);
3. Setting heating and cooling equipment to be always on for design days.

None of these applications are necessarily recommended but these and other uses of the special summer/winter design day schedules may prove useful for specific situations.

Some examples of common mistakes with design day data in schedules are:

1. Using a schedule such as the predefined **On** schedule for operating internal gains equipment such as [computers](#) or [lights](#). Internal gains must not be included in heating sizing calculations because the size of the heating equipment must be calculated without consideration of any contribution from internal gains. Including such gains usually results in undersizing of heating zone equipment and/or plant. Internal gains must of course be included in cooling sizing so should operate for the **SummerDesignDay**.
2. Selecting a [Heating operation schedule](#) on the [HVAC tab](#) with options indicating the schedule to be off for the **WinterDesignDay**. Or selecting a [Cooling operation schedule](#) on the [HVAC tab](#) with options indicating the schedule to be off for the **SummerDesignDay**. Likewise when using the [2-Detailed HVAC activity data](#) model option the heating and cooling setpoint schedules selected on the HVAC zone dialog must operate on their respective design day periods.

Sizing Factors

There are generally 2 areas of input where the user can impose *sizing factors*.

1. In [HVAC zone sizing data](#), the user can specify heating and cooling sizing factors for a specific zone. These factors are applied to the calculated zone design loads and air flow rates.
2. For some plant components (all central [chillers](#), [boilers](#) and [cooling towers](#)) the user can specify a sizing factor that modifies the autosized component capacity and flow rates. These factors are applied after zone sizing factors. They are primarily used to split the design load between multiple components. These sizing factors can change the autosizing of the associated loops and pumps. The following rules define the effect of plant component sizing factors on loops and pumps.
 - a. For supply side branches, the sizing factors of all components in series on the branch are summed and the result becomes the branch sizing factor. If there is a branch pump, its autosized design flow rate is multiplied by the branch sizing factor.
 - b. For each loop, if the average of the branch sizing factors is less than 1, the loop sizing factor is set equal to the sum of the branch sizing factors. If the average is greater than 1, the loop sizing factor is set equal to the maximum of the branch sizing factors. The loop sizing factor is applied to the loop design flow rate (if autosized) and to the loop pump flow rate (if autosized).

Mixing User-Specified and Autosized Inputs

Mixed user-specified and autosized inputs can be successfully used if the following points and suggestions are followed.

1. Each component is autosized independently. Thus user input for a flow rate in one component will have no effect on other components' autosized flow rates. For instance, specifying the chilled water loop pump's rated flow rate will have no effect on the autosizing of the chiller's design evaporator flow rate or on the plant loop's autosized maximum loop flow rate.
2. Within a component it is best to autosize all inputs or enter specified values for all inputs. For example, in a chiller, if only the nominal capacity is user-specified, the autosized chilled water flow rate may not be consistent with the specified capacity.
3. Sizing information flows only from the sizing data on the [HVAC zone](#), [Air loop](#) and [Plant loop](#) dialogs to the components. The sizing calculations have no knowledge of user-specified values in a component. The only exception to this rule is that plant loop sizing will collect all component design water flow rates whether autosized or user-specified.
4. To specify a particular zone or system air flow rate use the [HVAC Zone](#) and [Air Loop](#) data rather than in the individual components.
5. The plant loop flow rates are sized from the total design demand of the components connected to each loop. The components demanding water need not be autosized for the plant loop autosizing to work successfully. So the user could specify all the air side components and autosize all the plant loops and

plant components. Or specify the chilled water loop flow rate, chilled water pump inputs and chiller inputs and let the condenser loop and tower autosize.

Zone design flow rate inputs

In EnergyPlus the autosizing calculations start with a calculation of the zone design air flow rates using zone by zone design day simulations. The resulting zone design air flow rates and daily air flow sequences are used in the subsequent HVAC and central plant air and fluid flow design calculations and in the component autosizing calculations. The user can override or change the calculated zone design air flow rates in various ways.

1. The user can specify a separate zone level [Zone sizing factor](#) for [heating](#) and [cooling](#) for each [HVAC zone](#) object.
2. For each zone the user can input a [Cooling design air flow rate](#) and/or a [Heating design air flow rate](#) (and specify [Cooling design air flow method](#) = **1-Flow/Zone** and [Heating design air flow method](#) = **1-Flow/Zone**). These user inputs override the calculated values. The program divides the user input cooling or heating design air flow rate by the calculated values and uses the result as a zone sizing factor to multiply all the elements in the design heating and cooling air flow and load sequences. From this point the design calculations proceed as usual.

System design flow rate inputs

Using the results of the zone design air flow rate calculation (including any user input or altered flow rates) EnergyPlus proceeds to calculate central air system flow rates and cooling and heating loads. The results of this calculation can be overridden by setting the Air loop [Cooling design air flow method](#) to be **2-Flow/System** and input a value for [Cooling design air flow rate](#). Similarly for heating specify the [Heating design air flow method](#) to be **2-Flow/System** and input a value for [Heating design air flow rate](#).

HVAC Sizing Tips

To help achieve successful autosizing of HVAC equipment, note the following general guidelines:

- Begin with everything fully autosized (no user-specified values) and get a working system before trying to control any specifically sized components.
- You must coordinate system controls with sizing inputs. For example, if the Air loop [Central cooling design supply air temperature](#) is set to 13°C, you must make sure that the corresponding setpoint manager for the central cooling coil controls to the same 13°C as design conditions. EnergyPlus does not cross-check these inputs. The HVAC autosizing calculations use the sizing information in the [Air loop](#) and [HVAC zone](#) data. The simulation uses the information in controllers and setpoint managers.
- User-specified flow rates will only impact the sizing calculations if entered in the [Air loop](#) and [HVAC zone](#) data. Sizing information flows only from the sizing objects to the components. The sizing calculations have no knowledge of user specified values in a component. The only exception to this rule is that plant loop sizing will collect all component design water flow rates whether autosized or user specified.
- The zone thermostat schedules determine the times at which design loads will be calculated. All zone-level schedules (such as lights, electric equipment, infiltration) are active during the sizing calculations (using the day type specified for the sizing period). System and plant schedules (such as availability managers and component schedules) are unknown to the sizing calculations. To exclude certain times of day from the sizing load calculations, use the thermostat setpoint schedules for **SummerDesignDay** and/or **WinterDesignDay**. For example, setting the cooling setpoint schedule to 99°C during night-time hours for the **SummerDesignDay** day type will turn off cooling during those hours.

Differences Between Autosizing Simulations And Cooling Design Calculations

In general the zone heating and cooling loads displayed in the "HVAC Sizing Summary" table for the autosizing simulations should match closely with the equivalent values displayed on the Cooling design screen on the Summary tab. However some differences may be observed due to one or more of:

1. When using Detailed HVAC and the [Detailed HVAC activity data](#), the simulation setpoints and schedules are defined separately on the HVAC zone dialog and can easily be different to the setpoints

- defined on the Activity tab and to the schedules defined on the HVAC tab. When using the default Simple HVAC activity data option this difference is much less likely to occur.
2. The mechanical ventilation settings are defined on the HVAC tab for heating and cooling design calculations but they are defined on the Air loop dialog for autosizing simulations.
 3. The conditions of the supplied air is defined on the HVAC zone dialog for autosizing simulations whereas the data on the HVAC tab under [Supply air conditions](#) headers is used for heating and cooling design calculations.
 4. Cooling design calculations are run using 2 timesteps per hour whereas the cooling autosizing simulations are run using the number of timesteps selected for the simulation. The timestep difference doesn't arise for heating design where the inside and outside conditions are static.
 5. The **WinterDesignDay** settings control the operation for the heating autosizing simulations, whereas for Heating design calculations, fixed values are always used and there is less scope for obtaining "surprising" results. E.g. there is no way to include internal gains from occupants and equipment, whereas it is possible to include these gains (deliberately or inadvertently) in heating autosizing simulations through compact schedule settings.
 6. When the Calculated natural ventilation model option is selected this is used in autosizing simulations (if the relevant schedules allow it) whereas for Cooling design calculations the scheduled natural ventilation settings are used (if natural ventilation is enabled).
 7. Heat recovery can be activated or not for Cooling design calculations whereas it is *not* included when sizing zone loads in autosizing simulations.

Humidity Control

It is usually easiest to select an appropriate HVAC Template as the starting point when setting up humidity control for Detailed HVAC systems. However in some cases you may need to define humidity control manually and this page describes the steps involved.

The process depends on the base system type. The instructions below are for the [Simple HVAC activity data](#) option. When the [Detailed HVAC activity data](#) is used the process is similar but [humidistat setpoints](#) come from schedules defined on the HVAC zone dialog instead of [setpoint values](#) defined on the Activity tab and demand schedules on the HVAC zone dialog.

VAV With Reheat

To add humidification/dehumidification control to a VAV system, follow these steps:

Humidification

1. Add a [humidifier](#) to the AHU, typically as the rightmost component in the AHU (nearest to the supply end).
2. Set any sizing and capacity parameters on the [humidifier dialog](#).
3. On the supply loop level of the air loop add a [setpoint manager](#) *immediately downstream* of the humidifier and edit the setpoint manager type to use one of the "humidity minimum" setpoint managers. For example the [6-Multi-zone humidity minimum controller](#) calculates the supply air minimum humidity ratio based on the zone with the highest humidity ratio setpoint to maintain the zone RH levels near their respective humidifying setpoints. Setting up the setpoint manager in this way ensures that air leaving the humidifier has a minimum level of humidity required to meet the setpoint in the zone with the lowest RH. The screenshot below illustrates the components involved.

- When using one of the "humidity minimum" controllers you must switch on the [humidistat](#) option on the [HVAC zone](#) dialog and define RH setpoint schedules. Humidistats can provide a fine degree of humidification control within each zone. To define RH setpoint schedules enter the zone [Humidification setpoint](#) model data and [Humidifying demand schedule](#) on the HVAC zone dialog (when using Simple HVAC Activity Data) or the HVAC zone [Humidifying RH setpoint schedule](#) (when using Detailed HVAC Activity Data).
- An alternative approach which does not provide close control of zone humidity is to use a [1-Scheduled](#) Setpoint manager type and the [6-Minimum humidity ratio](#) Control variable. This simply ensures that the supply air has a minimum RH. In this case the HVAC zone humidifying setpoint settings are not used.

Dehumidification

- On the AHU [cooling coil](#) dialog when using water coils, to control both temperature and humidity, set the [Controller control variable](#) to **3-Temperature and Humidity Ratio**, or if no temperature control is required, select the **2-Humidity Ratio option**.

Edit Water Cooling Coil -

Water Cooling Coil

Control variable	2-Humidity ratio
Control action	2-Reverse
Actuator variable	1-Flow
Controller convergence tolerance (deltaC)	Autosize
Maximum actuated flow (m3/s)	Autosize
Minimum actuated flow (m3/s)	0

- Where a DX cooling coil is to conduct both temperature and humidity control, set the Coil Type to [2-Two stage with dehumidification](#) and set the [Dehumidification control type](#) to **2-Multi mode** or **3-Cool reheat**. For all dehumidification controls, one of the maximum humidity setpoint managers on the control node are used. The temperature and humidity setpoint managers must both be located on the same node. Assuming that the default temperature setpoint manager is already placed downstream of the AHU, add a new [setpoint manager](#) downstream of the AHU and edit the setpoint manager [Type](#) to use one of the "humidity maximum" setpoint managers. For example the [7-Multi-zone humidity maximum](#) controller calculates the supply air humidity ratio based on the zone with the lowest humidity ratio setpoint to maintain the zone RH levels near their respective humidity setpoints. Setting up the setpoint manager in this way ensures that air leaving the cooling coil has a maximum level of humidity, but on its own does not provide close control humidity in the zones.

Edit DX Cooling Coil -

- For all dehumidification systems currently supported by DesignBuilder it is essential to include some form of zone reheat to ensure that "overcooled" air from the AHU does not cause the zone to be overcooled. The zone reheat can be a standard [reheat ADU](#) or it can be some other form of [zone heater](#) such as a convector or radiator.

Note: The temperature setpoint managers [11-Single Zone Heating](#), [12-Single Zone Cooling](#), [13-Multi Zone Cooling Average](#) and [14-Multi Zone Heating Average](#) are not suitable for humidity control. For humidity control applications, use the [1-Scheduled](#), [2-Warmest](#), [3-Coldest](#), or [10-Outdoor Air Reset](#) instead.

Note: In cases where a VAV system uses a *water* cooling coil for dehumidification in the AHU, it is sometimes not possible to control upper zone humidity levels accurately. This situation is more likely under low load conditions when the VAV terminal box dampers are at minimum position and the water cooling coil cannot drop the air stream temperature to the level required for high humidity control. In such cases you may find that swapping the water coil for a [Cooling Coil - Two Stage with Humidity Control DX](#) helps because the lower coil temperatures and humidity control capability of this DX coil allow it to drop out more moisture from the air stream, helping to maintain the zone maximum humidity setpoint. Another possible solution to this problem is to increase the minimum flow fraction for the ADU to a higher than normal value, e.g. 0.5. This allows a greater volume of dry air from the AHU to be introduced into the zones, even when sensible loads are low.

The Humidification and Dehumidification set ups described above can be used together to achieve full humidity control.

HVAC Templates Illustrating Humidity Control

Three Detailed HVAC templates demonstrate how to model VAV systems with humidity control using different cooling approaches:

VAV Reheat, DX cooling with Dehumidification

This template uses a VAV reheat air handling unit with direct expansion (DX) cooling and dedicated dehumidification. The DX coil cools and dehumidifies the air, while a boiler supplies hot water to the reheat coils to maintain supply air temperature. The system includes separate setpoint managers for temperature and humidity, delivering conditioned air to the zone through a ducted VAV configuration.

HVAC Template Selection

Select an HVAC System

VAV Reheat, Air-cooled Chiller, Steam Humidifier

This template features a Variable Air Volume (VAV) reheat air handling unit with both cooling and humidity control. An air-cooled chiller supplies chilled water for cooling, while a boiler provides hot water for reheat coils. A steam humidifier is included in the air loop to maintain humidity levels. The air loop distributes conditioned air to the zone, ensuring both temperature and humidity control.

HVAC Template Selection

Select an HVAC System

VAV Reheat, Water-cooled Chiller, Full Humidity Control

This template demonstrates how to set up a VAV reheat system with water coils for full humidity control (humidification and dehumidification).

HVAC Template Selection

Select an HVAC System

To load an HVAC template, first go to the [HVAC System level](#) then click on the [Load HVAC Template](#) tool.

CAV With Reheat

The procedure for setting up humidity control in CAV systems is similar to that described for VAV systems above, except that there is less likely to be issues with achieving dehumidification setpoints during times of low sensible load. This is because there is no damper to reduce flow at the terminal unit so zones get access to the full flow of air from the AHU.

Unitary Heat Cool And Unitary Heat Pump Humidity Control

To add humidification/dehumidification control to a unitary heat cool system, follow these steps:

1. For each zone supplied by the unitary heat cool AHU, switch humidity control on by checking the [Humidistat control](#) check box on the HVAC zone dialog and define any time-varying demand schedules.

Dehumidification

1. Go down to the air loop supply sub-loop and edit the [AHU](#), changing the [Dehumidification control type](#) to **2-CoolReheat**.

2. Add a Maximum humidity [setpoint manager](#) downstream of the AHU (**5-Multi-zone maximum humidity average** or **7-Multi-zone humidity maximum** or **9-Single zone humidity maximum**).

Humidification

1. Add a [Humidifier](#) component to the AHU.
2. Add a Minimum humidity [setpoint manager](#) immediately downstream of the Humidifier (**4-Multi-zone minimum humidity average** or **6-Multi-zone humidity minimum** or **8-Single zone humidity minimum**).

HVAC Components

A range of component types are available with Detailed HVAC:

- "Loop Data" on page 729
- "Air Loop Components" on page 789
- "Plant Loop Heat Pumps" on page 864
- "Air to Water Heat Pump / ASHP Data" on page 886
- "Performance Curves" on page 898
- "Editing Zone Group Data" on page 926
- "Editing HVAC Zone Data" on page 928
- "Setpoint Manager" on page 940
- "DHW" on page 950
- "Solar Hot Water" on page 975
- "Plant and Condenser Loop Equipment Data" on page 980
- "Zone Unit Data" on page 1114
- "Heating and Cooling Coil Data" on page 1214
- "Generators" on page 1249

Air Loop Components

The following air loop components can be placed on the supply side of an air loop:

- "Air Handling Units" on page 789
- "Heating Coils " on page 1214
- "Cooling Coils" on page 1230
- "Plenum Data" on page 829
- "Fans" on page 830
- "Humidifier - Steam Electric" on page 846
- "Evaporative Cooler Data" on page 848

Air Handling Units

Air handling units (AHUs) are components that are automatically included in the supply sub-loops of all air loops. AHUs are composite units incorporating all of the components that comprise central air handling plant such as outdoor air mixers, fans, heating/ cooling coils and humidifiers. There are two main types of AHU in DesignBuilder HVAC, generic and unitary AHUs. The main difference between the two units is that unitary AHUs incorporate an EnergyPlus unitary system such as air-to-air heat pump or heat/cool unit.

To edit the data associated with an AHU, you first need to be at the supply sub loop level of the Air loop. Select the AHU component by moving the mouse cursor over it and then clicking the mouse button to select it. You can then access the edit dialog by right-clicking the mouse and selecting the Edit selected component option or alternatively, select the Edit selected component tool from the toolbar.

The following AHU types are available:

- [Generic AHU](#)
- "Unitary Generic AHU" on page 810
- [Unitary Heat Cool AHU](#)
- [Unitary Air to Air Heat Pump AHU](#)
- "Unitary Water To Air Heat Pump AHU" on page 824
- "DOAS AHU" on page 828

See the [Adding air loops and AHUs](#) tutorial

Generic Air Handling Unit (AHU)

The basic generic AHU incorporates an outdoor air system and a supply fan. There are also options for night cycle operation, a heat recovery system, an economiser, pre-heat and pre-cool coils and an extract fan. Additional components such as heating coils, cooling coils and humidifiers may also be added to generic AHUs.

See the [Adding air loops and AHUs](#) tutorial

General

Name

This is a unique, read-only label that is automatically generated by the software and which incorporates the name of the air loop in which the AHU is located.

Fan type

This setting is used to indicate a Constant Air Volume (CAV) or Variable Air Volume (VAV) system. It can take one of two values:

- **1-Constant volume** or
- **2-Variable volume.**

Note 1: Once an air loop has been connected to a zone ADU, the **Fan type** setting is fixed (greyed out) preventing an invalid connection and remains greyed out until the air loop is disconnected from all ADUs. So to change an air loop from VAV to CAV or vice-versa using this control you must first disconnect the demand side of the air loop from all zone ADUs. You can do this by deleting connecting branches.

Note 2: Once the AHU fan type has been set, the air loop containing the AHU can only be connected to valid [zone air distribution units](#) (ADU), i.e. CAV air loops can only be connected to CAV ADUs and similarly VAV systems can only be connected to VAV ADUs.

Design supply air flow rate

This is the air loop primary air design volumetric flow rate (in m3/s or ft3/min). This setting is auto-sizeable.

Operation

Availability schedule

This schedule contains information on the availability of the AHU for operation. A schedule value greater than 0 (1 is usually used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

When this unit is unavailable (schedule values of 0) then all equipment contained within this AHU will also be switched off.

Night Cycle

This setting can be used to enable cycling of an air system when one or more zones become too hot or too cold. A common requirement for this mechanism is where the AHU is turned off at night. However if the building gets too cold there might be condensation on the walls and other damage. So control systems are usually programmed to turn the system on either if a specified control thermostat or any thermostat shows a zone temperature of less than a night time set point. Similarly, there might be a concern about a building getting too hot. Again the control system is programmed to turn the AHU back on if one or any zone temperature exceeds a night time cooling set point.

This mechanism offers flexibility in determining how the nighttime on/off decision will be made. The temperature in one specific zone may be used or the temperatures in all the zones connected to the AHU may be sampled. You can specify a temperature tolerance and a run time for the system once it switches on. There is also an applicability schedule for scheduling when this mechanism may be applied.

Applicability schedule (night cycle)

This schedule determines whether or not for a given time period this mechanism is to be applied. Schedule values greater than zero (usually 1 is used) indicate the night cycle mechanism is to be applied, whereas schedule values less than or equal to zero (usually 0 is used) denote that it is not used for this time period.

Control type

The possible inputs are:

- **1-Stay off** means the night cycle mechanism will have no effect – AHU on/off will be determined by the fan schedule
- **2-Cycle on any** means that if any zone served by the air loop incorporating this AHU has an air temperature outside the cooling or heating set points the central fan will turn on even though the fan schedule indicates the fan is off.
- **3-Cycle on control zone** means the same thing except that the temperature in only the specified control zone is used.
- **4-Cycle on any zone fans only** is the same as **2-Cycle on any** except that only the zone fans are cycled on and the AHU fan is left off.

Important Note: Plant loops and any required zone units must be available during the night cycle by amending the availability schedules appropriately. The night cycle availability manager only automatically overrides the air loop fan schedule.

Thermostat tolerance

This is the amount (in °C or °F) by which the zone temperature must exceed the cooling set point or fall below the heating set point in order for the night cycle mechanism to signal that the system should turn on.

Cycling run time

The time in seconds for which the system will run after it has cycled on. The default is 3600 seconds (1 hour).

Control zone

For the Control Type option **3-Cycle on control zone** select the control zone.

Extract Fan

Include extract fan

An extract fan is included within all AHUs by default. This setting may be used to remove the extract fan from the AHU.

Note: If the AHU is connected to a zone that incorporates a Variable Air Volume with Reheat and Variable Speed Fan ADU, the AHU extract fan should be omitted otherwise EnergyPlus will raise an error and the simulation will be aborted.

Mixed Mode

You can set up Mixed mode controls for the AHU to model optimal interaction between the natural ventilation system (Scheduled or Calculated) and the AHU.

Refer to the main HVAC tab [Mixed Mode](#) section for details on the options available.

Note: If mixed mode is activated here on the AHU dialog, then any mixed mode settings for connected zones on the HVAC tab will be overridden by these mixed mode settings.

Outdoor Air System (Common To All AHUs)

The outdoor air system incorporates an air mixer, an optional pre-cool coil, an optional pre-heat coil, an optional heat recovery device and an outdoor air controller. The purpose of the outdoor air controller is to provide outdoor air for ventilation and also provide free cooling (through additional outdoor air and/or bypassing an air-to-air heat exchanger) whenever possible. The outdoor air controller includes a number of user-selectable limit controls. If any of the selected limits are exceeded, the outdoor airflow rate is set to the minimum.

If all the limits are satisfied, the outdoor air controller does the following for continuous air flow systems: if the outdoor air temperature is greater than or equal to the mixed air temperature setpoint, the outdoor air flow rate is set to the maximum; if the outdoor air temperature is less than the mixed air temperature setpoint, the outdoor air controller will modulate the outdoor air flow so that the mixed air temperature will match the mixed air setpoint temperature.

A time-of-day schedule may also be used to simulate an increase in outdoor air flow rate for “push-button” type economiser applications. When the schedule permits (i.e., schedule values are greater than 0), the outdoor air flow rate is increased to the user-specified maximum outdoor air flow rate.

The outdoor air controller can also account for changes in the outdoor air flow rate during times when indoor humidity levels are high. A zone humidistat must be used with this control option. During high indoor humidity, the outdoor air flow rate is modified in response to a high indoor humidity condition. If high humidity control is based on the outdoor air humidity ratio and the outdoor humidity ratio is greater than the indoor humidity ratio, high humidity control is terminated. When the economiser is used in conjunction with the high humidity control option, high humidity control has priority and controls the change in air flow rates. If the AHU Night Cycle option is switched on, it has priority over high humidity control and will use the controller’s maximum outdoor air flow rate when the Night Cycle mechanism cycles the fan on.

Optional pre-cool coil, pre-heat coil and heat recovery may be specified upstream of the mixer. When this is the case, any modulation will be determined by the conditions at the inlet node of the mixer rather than the outdoor air. This means that the controller will account for the heat recovery device or pre-heating/pre-cooling coils that may modify the condition of outdoor air before it reaches the mixer. If all the limits are satisfied, the outdoor air controller does the following for cycling fan systems: the outdoor air flow rate is set to the maximum when the fan cycles on. If the limits are not satisfied, the outdoor air flow rate is at the minimum when the fan cycles on.

Minimum limit type 2-Fixed minimum

Economiser (Free Cooling)

Economiser control type 1-No economizer

Outdoor Air Schedules

☐ Apply minimum outdoor air schedule

☐ Apply minimum fraction of outdoor air schedule

☐ Apply maximum fraction of outdoor air schedule

Demand Controlled Ventilation

☐ Demand controlled ventilation

Heat Recovery

☐ On

If this option is checked, the AHU will re-circulate a proportion of the air delivered by the AHU, otherwise the system will operate as a full fresh air system.

Full Fresh Air with Economiser

If you need to model a full fresh air system with no recirculation but need some of the functionality under the Recirculation check box, such as an economiser, you should check the Recirculation checkbox and make the following settings:

- Check the [Apply minimum fraction of outdoor air schedule](#) checkbox and select the **On 24/7** schedule as the [Minimum fraction of outdoor air schedule](#).
- Check the [Apply maximum fraction of outdoor air schedule](#) checkbox and select the **On 24/7** schedule as the [Maximum fraction of outdoor air schedule](#).

The screenshot below shows how the data should look when you are finished.

Outdoor Air Schedules

☐ Apply minimum outdoor air schedule

☒ Apply minimum fraction of outdoor air schedule

 Minimum fraction of outdoor air schedule On 24/7

☒ Apply maximum fraction of outdoor air schedule

 Maximum fraction of outdoor air schedule On 24/7

These settings ensure that the fraction of fresh air is 1 at all times and that there is no recirculation.

Minimum outdoor air flow rate

This is the minimum outdoor air flow rate that the system can supply (in m3/s or ft3/min).

This value should be set to zero when using DCV and to **Autosize** when the Minimum outdoor air flow rate is to be autosized.

Maximum outdoor air flow rate

This is the maximum outdoor air flow rate for the system (in m³/s or ft³/min).

Minimum limit type

Choices for this field are:

- **1-Proportional minimum** which means the minimum outdoor airflow rate varies in proportion to the total system air flow rate
- **2-Fixed minimum** which means that the minimum outdoor airflow rate is fixed no matter what the actual system flow rate is.

Economiser

An economiser can be included to provide free cooling by increasing the flow of outdoor air into the AHU mixing box when conditions are favourable. The types of economiser available are:

- **1-No Economiser** - the economiser will not operate and the outdoor airflow rate will be at the minimum for the entire simulation.
- **2-Fixed Dry-Bulb** - the economiser will set the outdoor airflow rate at minimum if the outdoor air temperature is higher than a specified dry-bulb temperature limit.
- **3-Differential Dry-Bulb** - will trigger the outdoor airflow to minimum when the dry-bulb temperature of outdoor air is higher than the dry-bulb temperature of the return air.
- **4-Fixed Enthalpy** - checks the upper limit of the enthalpy given as a field input against the enthalpy content of outdoor air and will set the outdoor airflow rate to minimum if the latter is greater than the former.
- **5-Differential Enthalpy** does the same as **4-Fixed Enthalpy** but compares the return air enthalpy with the enthalpy of outdoor air. When the enthalpy of outdoor air is greater than the enthalpy of the return air, the outdoor air flow rate is set to minimum.
- **6-Electronic Enthalpy** enables the simulation to calculate the humidity ratio limit of outdoor air based on the dry-bulb temperature of outdoor air and a quadratic/cubic curve, and compare it to the actual outdoor air humidity ratio. If the actual outdoor humidity ratio is greater than the calculated humidity ratio limit, then the outdoor airflow rate is set to minimum.
- **7-Fixed Dew-Point and Dry-Bulb** compares both the outdoor dew-point temperature and the outdoor dry-bulb temperature to their specified high limit values. If either outdoor temperature exceeds the high limit value, the outdoor airflow rate is set to minimum.
- **8-Differential Dry-Bulb and Enthalpy** enables the control strategy to be based on both the **3-Differential Dry Bulb** and **5-Differential Enthalpy** economiser control strategies.

In addition to all economiser control types listed above, each control type checks for user-entered values for the upper limit of dry-bulb temperature, enthalpy limit, humidity ratio limit and dew-point limit. The outdoor air flow rate is set to minimum if any of these entered limits are exceeded.

Note: The economiser acts to control the *temperature* of the mixed air stream regardless of the type of economiser.

The way that the economiser air flow rate is controlled is illustrated in the diagram below.

Economiser optimiser control action

- The **Min. Limit DB** temperature on the graph above is set using the [Economiser minimum limit dry-bulb temperature](#) setting and when the **OA Temperature** is below this value, the **OA Flow Rate** is set to minimum.
- The **Mixed Air SP** temperature is obtained by EnergyPlus from a mixed air [Setpoint Manager](#) which is automatically created by DesignBuilder using the setpoint defined for the first cooling SPM downstream from the AHU air mixing box.
- When the **OA Temperature** is less than the **Mixed Air SP**, the controller modulates the OA flow rate so as to maintain the **Mixed Air SP**.
- The **Max. Limit DB** is set using the [Economiser maximum limit dry-bulb temperature](#) setting (which is only be available on the dialog for **2-Fixed Dry Bulb** and **7-Fixed Dew Point And Dry Bulb** economiser control types).
- When the **OA Temperature** is between the **Mixed Air SP** and the **Max Limit DB**, the OA controller sets the OA flow rate to maximum.
- When the OA temperature reaches the **Max. Limit DB**, the OA controller sets the **OA Flow Rate** to minimum.

When the economiser control type is set to **4-Fixed Enthalpy**, the **Max. Limit DB** would be replaced by the enthalpy value entered for the [Economiser maximum limit enthalpy](#) setting, i.e. instead of switching the OA flow to minimum when the OA temperature reaches the specified maximum, it would switch to minimum when the OA enthalpy reaches the specified maximum. The optimiser is still working though to maintain the setpoint temperature for the mixed air stream.

Note: A cooling or scheduled temperature setpoint manager must be included on the supply side of the air loop when an economiser is selected. This will typically be downstream of the AHU.

Economiser control action type

There are two choices:

- **1-Modulate flow** which means that the outdoor air flow rate will be increased to meet the mixed air setpoint temperature, subject to the limits imposed via other inputs for this object (e.g., Economizer Maximum Limit Dry-Bulb Temperature, Maximum Outdoor Air Flow Rate, etc.).
- **2-Minimum flow with bypass**, which is only available if Heat Recovery is selected. This option is used in conjunction with a heat recovery device for providing free cooling operation in the absence of a conventional air-side economizer (i.e., when outdoor air flow rate is not increased during economizer mode). It forces the outdoor air flow rate to always remain at the minimum. However, when high humidity control is used, the outdoor air flow rate is set to the product of the maximum outdoor air flow

rate multiplied by the high humidity outdoor air flow ratio. The heat exchanger uses the limit checking in the outdoor air controller to decide whether or not to bypass the outdoor air around the heat exchanger – or turn off the wheel motor in the case of a rotary heat exchanger. Heat exchange is also suspended when high humidity control is active. When **2-Minimum flow with bypass** is used and the [Time of day economizer control schedule](#) value is 0, then the flow is set to the minimum. If the time of day schedule is not used, then flow is always at minimum. If there is no economizer, the flow is always at minimum. If there is an economizer, this data either maintains flow at minimum when bypassing or not.

Lockout type

Choices for this setting are:

- **1-No lockout**,
- **2-Lockout with heating**, which means that if the packaged unit is in heating mode, the economiser is locked out – i.e. the economizer dampers are closed and there is minimum outdoor air flow.
- **3-Lockout with compressor**. This setting only applies to unitary systems with DX coils and means that in addition to locking out the economiser when the unit is in heating mode the economiser is locked out when the DX unit compressor is operating to provide cooling. In other words, the economiser must meet the entire cooling load – it isn't allowed to operate in conjunction with the DX cooling coil. The **3-Lockout with compressor** option is sometimes called a “non-integrated” economiser.

Economiser minimum limit dry-bulb temperature

This is an optional outdoor air temperature low limit (in °C or °F) for economiser operation. If the outdoor air temperature is below this limit, the outdoor airflow rate will be set to the minimum. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Economiser maximum limit dry-bulb temperature

This is an optional outdoor air temperature high limit (in °C or °F) for economiser operation. If the outdoor air temperature is above this limit, the outdoor airflow rate will be set to the minimum. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Economiser maximum limit enthalpy

This is an optional outdoor air enthalpy limit (in J/kg or Btu/lb) for economiser operation. If the outdoor air enthalpy is above this value, the outdoor airflow rate will be set to the minimum. This field is required if the Economiser type is set to **4-Fixed enthalpy**. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Economiser maximum limit dew-point temperature

This is an optional outdoor air dew-point limit (in °C or °F) for economiser operation. If the outdoor air dew-point temperature is above this value, the outdoor airflow rate will be set to the minimum. This limit applies to the conditions at the Actuator Node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Electronic enthalpy limit curve

This is an optional [Quadratic](#) or [Cubic](#) curve which provides the maximum outdoor air humidity ratio (function of outdoor air dry-bulb temperature) for economiser operation. If the outdoor air humidity ratio is greater than the curve's maximum humidity ratio (evaluated at the outdoor air dry-bulb temperature), the outdoor air flow rate will be set to the minimum. This limit applies to the conditions at the Actuator node regardless of whether or not there are any other components in the outdoor air path upstream of the mixer.

Time of day economiser control schedule

This is an optional schedule which controls the outdoor air flow rate based on a time-of-day economiser. Schedule values equal to 0 disable this feature. A schedule value of greater than 0 causes the outdoor air flow rate to increase to the maximum. When an economiser is used in conjunction with the high humidity control option, high humidity control has priority.

High humidity control

This setting establishes whether or not the outdoor air flow rate is modified in response to high indoor relative humidity. If **2-Yes** is selected, the outdoor air flow rate may be modified when the indoor relative humidity is above the humidistat setpoint. If **1-No** is selected, this option is disabled and the following three settings are not displayed.

Humidistat Control Zone

This is the zone name where the humidistat is located. This setting is only required when the High Humidity Control is set to **2-Yes**.

High humidity outdoor air flow ratio

This is the ratio of the modified outdoor air flow rate to the maximum outdoor air flow rate. When the high humidity control algorithm determines that the outdoor air flow rate will be changed (i.e. increased or decreased), the operating outdoor air flow rate is equal to the maximum outdoor air flow rate multiplied by this ratio. The minimum value for this setting is 0. This setting is only required when the [High humidity control](#) is set to **2-Yes**. When an economiser is used in conjunction with the high humidity control option, high humidity control has priority.

Control high indoor humidity based on outdoor humidity ratio

This setting determines if high humidity control is activated based on high indoor relative humidity alone or is activated only when the indoor relative humidity is above the humidistat setpoint and the indoor humidity ratio is greater than the outdoor humidity ratio. Valid choices are **1-Yes** and **2-No**. If **2-No** is selected, high humidity control is active any time the zone humidistat senses a moisture load. If **1-Yes** is selected, the model also verifies that the outdoor humidity ratio is less than the humidistat's zone air humidity ratio. This setting is only required when the High Humidity Control is set to **2-Yes**.

Note: While conditions may be favourable for economizer operation, it does not guarantee that the air-side economizer has increased outdoor air flow above the minimum level since the actual outdoor air flow rate is also governed by other controls (e.g., mixed air set point temperature, time of day economizer control, maximum humidity setpoint, etc).

Outdoor Air Schedules

If the minimum outdoor air flow rate is to be scheduled then use one or both of the minimum outdoor air schedule or minimum fraction of outdoor air schedule settings described below.

- **Apply minimum outdoor air schedule** - to apply a schedule whose values are multiplied by the minimum outdoor air flow rate to calculate the outdoor fresh air rate at any time during the simulation. In this case you can select the **Minimum outdoor air schedule** below.
- **Apply minimum fraction of outdoor air schedule** - to apply a schedule whose values are multiplied by the total (design) air flow rate to calculate the outdoor fresh air rate at any time during the simulation. In this case you can select the **Minimum fraction of outdoor air schedule** below.

Scheduling Variable Outdoor Air

The screenshot below shows how to change the AHU Outdoor Air Schedule settings to obtain outdoor air varying between the maximum value defined on the HVAC tab and zero based on occupancy schedule "Office_OpenOff_Occ", in the same way as it does with Simple HVAC.

Outdoor Air Schedules	
☒ Apply minimum outdoor air schedule	
 Minimum outdoor air schedule	Office_OpenOff_Occ
☐ Apply minimum fraction of outdoor air schedule	
☐ Apply maximum fraction of outdoor air schedule	

When outdoor air delivery to zones is to be controlled accurately as described above it is necessary to make 3 further settings:

1. When using the [VAV with Reheat](#) and [VAV with no Reheat](#) terminal units in the way described above then it is also necessary to select the [Control on outdoor air flow](#) option in these 2 dialogs.
2. It is also necessary to use the **2-Fixed minimum** [Minimum limit type](#) on the AHU dialog.
3. Ensure that the [Minimum outdoor air flow rate](#) is set to **Autosize** and not zero. Note that this is the opposite of the requirement for DCV.

It is important to understand that even with the above settings you won't generally obtain exact specified outdoor air flow rates *to individual zones*, however the *total fresh air supply rate provided through the AHU* should be correctly calculated as the sum of the minimum fresh requirements of all zones served by the AHU. This is because the total outdoor air requirement for each zone on the air handler is summed and used to set the minimum total outdoor air flow rate for the air handler. The outdoor air controller sets an outdoor air flow rate for the air handler at each time step during the simulation. After that, each zone receives a pro-rated share of the total outdoor air flow proportioned by the current supply flow rate to each zone, but the exact supply flow rate to each zone will be calculated based on cooling or heating demand not fresh air requirements and there is no further zone-by-zone allocation of outdoor air quantities - which is what happens in a real system.

Apply minimum outdoor air schedule

Check this checkbox if you wish to apply a **Minimum outdoor air schedule** limit in which case the schedule can be selected in the browse list below.

Minimum outdoor air schedule

When the **Apply minimum outdoor air schedule** checkbox is checked you can select this schedule which uses decimal values (0.0 – 1.0). These values are multiplied by the minimum outdoor air flow rate. This schedule is useful for reducing the outdoor air flow rate to zero during unoccupied or start up hours. If this schedule option is not used, the minimum outdoor air flow rate either remains constant during the simulation period ([Minimum limit type](#) = **2-Fixed minimum**) or varies in proportion to the supply air flow rate ([Minimum limit type](#) = **1-Proportional minimum**).

Apply minimum fraction outdoor air schedule

Check this checkbox if you wish to apply a **Minimum fraction of outdoor air schedule** limit in which case the schedule can be selected in the browse list below.

Minimum fraction of outdoor air schedule

When the **Apply minimum fraction of outdoor air schedule** checkbox is checked you can select this schedule which uses decimal values (0.0 – 1.0). These values are multiplied by the design supply air flow rate. This is an alternate method for specifying the minimum outdoor air amount. The other method is the [Minimum outdoor air schedule](#) described above.

Note: If both the **Minimum outdoor air schedule** and the **Minimum fraction of outdoor air schedule** are both selected then for each timestep of the simulation, the higher of the two minimum limits is calculated and applied. Both of these settings act by overriding the [Outdoor air flow rate](#).

Apply maximum fraction of outdoor air schedule

Check this option to limit the maximum outdoor air flow rate.

Maximum fraction of outdoor air schedule

When the above **Apply maximum fraction of outdoor air schedule** option is selected you can also select the corresponding schedule which has fractional values in the range 0.0-1.0. This schedule effectively enables you to limit the maximum amount of outdoor air into the system.

Demand Controlled Ventilation

Ventilation standards provide guidance on appropriate levels of outdoor ventilation air required for acceptable indoor air quality. For example the Ventilation Rate Procedure (VRP) of ASHRAE Standard 62.1-2007/2010 requires outdoor ventilation rates to be determined based on the floor area of each occupied zone plus the number of people in each zone and considers the zone air distribution effectiveness and system ventilation efficiency. The outdoor air ventilation rate can be reset dynamically as operating conditions change (e.g. variations in occupancy).

The VRP option can be used for calculating these outdoor air ventilation requirements and resetting them based on varying occupancy levels and zone diversification. This is particularly useful for large air distribution systems that serve a number of different zone types with varying occupancy levels.

DCV control can also be used to model the Indoor Air Quality Procedure (IAQP) as defined in Standard 62.1

Demand controlled ventilation

Check this option to include DCV controls for this AHU.

System outdoor air method

Select the method to be used to calculate the system minimum outdoor air flow. The following options are available:

- **1-Zone sum** - sums the outdoor air flows across all zones served by the system.
- **2-Standard 62.1 ventilation rate procedure** - uses the multi-zone equations defined in 62.1-2007 to calculate the system outdoor air flow. VRP considers zone air distribution effectiveness and zone diversification of outdoor air fractions.
- **3-Standard 62.1 ventilation rate procedure with limit** - is similar to **2-Standard 62.1 ventilation rate procedure**. The only difference between the two methods is that **3-Standard 62.1 ventilation rate procedure with limit** - doesn't allow the system outdoor air flow to be larger than the design value.
- **4-Indoor Air Quality Procedure (IAQP)** - the other procedure defined in ASHRAE Standard 62.1-2007 for calculating the amount of outdoor air necessary to maintain the levels of indoor air carbon dioxide at or below a setpoint. Setpoints are defined on the Activity tab ([Simple HVAC activity data](#) option) or on the HVAC zone dialog ([Detailed HVAC activity data](#) option). Outdoor air intake and other system design parameters are based on an analysis of contaminant sources, and contaminant concentration targets. EnergyPlus uses the IAQP to control carbon dioxide and allows credit to be taken for controls that can be demonstrated to result in indoor carbon dioxide and generic contaminant concentrations equal to or lower than those achieved using the VRP. The IAQP may also be used where the design is intended to attain specific target carbon dioxide and generic contaminant levels.
- **5-Proportional control based on design occupancy** - where the required outdoor air flow rate varies in proportion to the percentage of the CO₂ signal range. This variant of the proportional method uses the design occupancy to calculate outdoor air rate. This is usually a more realistic control strategy for real systems, which don't have access to real time occupancy data. This option should generally used for design stage simulations.
- **6-Proportional control based on occupancy schedule** described in Appendix A of the ASHRAE 62.1-2010 user's manual discusses another method for implementing CO₂-based DCV in a single zone system where the required outdoor air flow rate varies in proportion to the percentage of the CO₂ signal range. This variant of the proportional method uses the real occupancy at the current time step to calculate outdoor air rate. This is a good approach to estimate outdoor air rate in special applications where the zone controller has access to the real time occupancy information.
- **7-Indoor Air Quality Procedure (IAQP) generic contaminant** calculates the amount of outdoor air necessary to maintain the levels of indoor air generic contaminant at or below the setpoint defined on the Activity tab ([Simple HVAC activity data](#) option) or on the HVAC zone dialog ([Detailed HVAC activity data](#) option).
- **8-Indoor air quality procedure combined** uses the maximum of the required outdoor airflow for CO₂ IAQP and generic contaminant IAQP. Both CO₂ and generic contaminant models must be active when selecting this option.
- **9-Proportional control based on design outdoor air rate** - uses design outdoor air flow rate to calculate demand outdoor air flow rate.

Note: If either **1-Zone sum**, **2-Standard 62.1 Ventilation Rate Procedure (VRP)** or **3-Standard 62.1 ventilation rate procedure with limit** options are selected here then the [CO2 and contaminant](#) option must not be selected on the HVAC zone dialog.

Note: If either **4-Indoor Air Quality Procedure (IAQP)**, **7-Indoor Air Quality Procedure (IAQP) generic contaminant** or **8-Indoor air quality procedure combined** are selected then the [CO2 and contaminant](#) option must be selected for at least one HVAC zone connected to the AHU.

Note: When one of the proportional control methods is selected (**5-Proportional control based on design occupancy**, **6-Proportional control based on occupancy schedule** or **9-Proportional control based on design outdoor air rate**) then selection of the [CO2 and contaminant](#) HVAC zone options is optional. If zone minimum CO2 concentration settings for proportional control are to be specified then you should check it, otherwise leave it unchecked.

Note: When using DCV you should ensure that the [Minimum outdoor air flow rate](#) is set to zero and not to **Autosize**. This is the opposite of the requirement when [scheduling outdoor air flow without using DCV](#).

A [summary guide](#) on the steps required to model DCV is provided in the Modelling advice section.

For more details on how DCV is simulated in EnergyPlus see the [DCV page](#) in the EnergyPlus Engineering Reference Guide.

Zone maximum outdoor air fraction

For VAV systems, when a zone requires outdoor air higher than the user specified Zone Maximum Outdoor Air Fraction, the zone supply air flow will be increased (if damper not fully open yet) to cap the outdoor air fraction at the maximum value. This allows the system level outdoor air flow to be reduced while the total supply air flow increases to meet zone outdoor air requirement. Valid values are from 0 to 1.0. Default is 1.0 which indicates zones can have 100% outdoor air maintaining backward compatibility. This inputs work for single and dual duct VAV systems.

Availability schedule

Select the schedule which defines when DCV should operate. If the schedule's value is 0.0, then mechanical ventilation is not available and flow will not be requested. If the schedule's value is > 0.0 (usually 1 is used), mechanical ventilation is available.

Tip: This schedule can be useful for purging the building of contaminants prior to occupancy (i.e., ventilation rate per unit floor area will be provided even if the occupancy is zero).

Interaction with normal outdoor air control

The minimum quantity of outdoor air delivered via the mixed air box will be the greater of:

- The minimum outdoor air flow rate calculated by the normal (non-DCV) outdoor air method based on the settings on the HVAC and Activity tabs, and,
- The outdoor air flow rate calculated by the DCV

The actual outdoor air flow rate may be higher than the minimum if free cooling is available. Regardless, the outdoor air flow rate will not exceed the [Maximum outdoor air flow rate](#)

Heat Recovery (Common To All AHUs)

If this option is checked, the AHU will incorporate a sensible and latent air-to-air heat recovery device capable of both heating and cooling the supply air stream using waste energy from the exhaust side.

Heat exchanger performance can be specified to transfer sensible energy, latent energy or both between the supply and exhaust air streams. The input requires no geometric data. Performance is defined by specifying sensible and/or latent effectiveness at 75% and 100% of the nominal (rated) supply air flow rate at two operating conditions as shown in the following table:

Parameter	Conditions	
	Heating	Cooling
Entering supply air temperature:		
Dry-bulb	1.7°C (35°F)	35°C (95°F)
Wet-bulb	0.6°C (33°F)	26°C (78°F)
Entering exhaust air temperature:		
Dry-bulb	21°C (70°F)	24°C (75°F)
Wet-bulb	14°C (58°F)	17°C (63°F)

Operating Conditions for Defining Heat Exchanger Performance.

Note: Conditions consistent with the Air-Conditioning and Refrigeration Institute's (ARI) Standard 1060-2001

Heat exchange between the supply and exhaust air streams occurs whenever the unit is scheduled to be available (Availability schedule) and supply/exhaust air flow is present. Heat recovery can be used in conjunction with a conventional air-side economiser (select **1-Modulate flow** for the Economiser control action type), whereby heat exchange is suspended whenever the air-side economiser (or high humidity control) is active (i.e. air flow is fully by-passed around a fixed-plate heat exchanger or the rotation of a rotary heat exchanger is stopped). It is also possible to suspend heat exchange for the purpose of providing free cooling operation in the absence of a conventional air-side economizer (i.e. specify **2-Minimum flow with bypass** for the Economiser control action type). During winter weather, humid exhaust air entering the heat exchanger can form frost on the cold heat exchanger surfaces, which can reduce air flow and the amount of energy recovery. Several methods are used to control or eliminate frost formation, and the following types can be modelled for this heat exchanger object: supply air pre-heat, minimum exhaust air temperature, exhaust air recirculation and exhaust only. For preheat frost control, the Pre-heat Coil option must be checked under the Pre-Treatment header. The other frost control types may be selected using the [Frost control type](#) drop-list.

Air-to-air heat exchangers are sometimes controlled to maintain a fixed supply air outlet temperature to avoid overheating. DesignBuilder provides an [option](#) to model this control in EnergyPlus by automatically including a [Setpoint manager](#) to establish a temperature set point at the supply air outlet node of the heat exchanger. Wheel speed modulation or plate supply air bypass is used to control the supply air exiting conditions to this set point. The set point for supply air temperature control should be set at the minimum economizer temperature set point if an air-side economizer is also being used by the air system. If frost control and supply

air outlet temperature control are used, frost control takes precedence over supply air temperature control (e.g. Control defrost time fraction is determined as if wheel speed modulation or plate supply air bypass is not used).

Heat recovery control tips

The 4 methods listed below are can be used to help control heat recovery systems.

Note: Although an economiser is included in some methods, its main purpose is to provide control of the heat recovery and not free cooling. If effective free cooling is required then you should consider using the **1-Modulate flow** economiser option.

Control method 1: Scheduled heat recovery heating setpoint: When using heat recovery with [Supply air outlet temperature control](#) and without an economiser the heat recovery unit heats the outside air up to the heat recovery setpoint and no higher while the outside air temperature is below the setpoint. The heat recovery unit is bypassed when the temperature setpoint is satisfied. When the outside air temperature rises above the heat recovery setpoint the heat exchanger is not bypassed running at full capacity and heating the air as much as possible. This can lead to high supply temperatures when it is warm outside. Overall this control method works well for lower outdoor air temperatures but not so well in summer.

Control method 2: Fixed heating setpoint with economiser: To avoid the overheating caused by Control method 1 an economiser can be introduced with the following settings:

- Economiser control type = **2-Fixed dry bulb**
- Outdoor dry-bulb temperature low limit control = On
- Economiser maximum limit dry-bulb temperature = Fixed heat recovery setpoint temperature, e.g. 12°C.
- Economiser control action type = **2-Minimum flow with bypass**
- Heat recovery bypass control type = **1-Bypass when within economiser limits**
- Heat recovery Supply air outlet temperature control = **2-Yes**

This works well reducing overheating relative to method 1, but it only provides a single fixed heat recovery setpoint temperature for the year which makes it difficult to achieve optimal control.

Control method 3: Heat recovery outdoor air temperature setpoint: Another approach to controlling heat recovery is to use the heat exchanger only when the outside air temperature is below a setpoint, and for warmer outside conditions bypass the heat recovery unit. The following settings achieve this:

- Economiser control type = **2-Fixed dry bulb**
- Outdoor dry-bulb temperature low limit control = On
- Economiser maximum limit dry-bulb temperature = 50 (high value to avoid heat recovery operation during warm conditions)
- Economiser control action type = **2-Minimum flow with bypass**
- Heat recovery bypass control type = **1-Bypass when within economiser limits**
- Heat recovery Supply air outlet temperature control = **1-No**
- Economiser lockout = **1-Yes**

Control method 4: Use EMS. An EMS program can be written to control the heat recovery unit in a more optimal way. An example script is shown below which is based on Control method 1 but overrides the HR setpoint temperature and/or availability schedules to simulate a control system which provides the full benefit of HR in winter and bypasses the heat exchanger in warmer conditions when HR is not required:

```
!- EMS Program: HR Optimal Control Strategy 2 - Stepped HR Setpoint + Zone Temp Sensing

ELSEIF TempBlock1Zone1 > 23,
Set OverrideHRAvailability = 0, ! avoid HR when room temp more than 23
ELSE,
Set OverrideHRAvailability = 1, ! Otherwise HR is available
ENDIF;

```

Other possibilities include checking for zone heating and/or cooling loads to help ensure optimal HR setpoints.

Nominal supply air flow rate

The nominal primary side (supply) air flow rate (in m3/s or ft3/min). The actual supply and exhaust air flow rates must be between 50% and 130% of this value or a warning will be issued.

Nominal electric power

This is the electric consumption rate of the device (W). Electric power is considered constant whenever the unit operates. This numeric input can be used to model electric power consumption by controls (transformers, relays, etc.) and/or a motor for a rotary heat exchanger. None of this electric power contributes thermal load to the supply or exhaust air streams. The default value for this field is 0.

Heat recovery bypass control type

This selection determines whether specialized control is to be used to optimise the use of heat recovery when combined with an economiser. Options are:

- **1-Bypass when within economizer limits** - The default option where heat recovery is disabled any time the controller determines that the economizer is active (i.e. all economiser controls are within limits). Note that in cases where the economiser is selected but no economiser limits are defined then the heat recovery will always be bypassed.
- **2-Bypass when OA flow greater than minimum** - EnergyPlus checks whether the economizer is active and also whether the outdoor air flow rate is greater than the minimum, if so heat recovery is disabled. This means that heat recovery is active any time the outdoor air flow rate is equal to the minimum even when the economizer requests free cooling. For this case, the use of Supply air outlet temperature control for the heat exchanger is recommended (see below).

Supply air outlet temperature control

This data determines if the heat exchanger's supply air outlet is controlled to a temperature set point. The choices for this input field are **1-Yes** or **2-No**, with the default being **2-No**. When supply air outlet temperature control is used, the wheel rotational speed modulates or supply air is bypassed around the plate heat exchanger to maintain the desired setpoint temperature.

When **1-Yes** is selected you can enter the setpoint temperature to be used in the next text box below. In this case DesignBuilder automatically adds a scheduled [Setpoint manager](#) at the heat recovery supply air outlet node using the entered set point temperature. When an air-side economizer is also being modelled for this air system, the set point for the supply air outlet temperature control is forced to be equal to the [Economizer minimum limit dry-bulb temperature](#).

Supply air outlet setpoint temperature schedule

When **1-Yes** is selected for [Supply air outlet temperature control](#) you can select a time-varying setpoint temperature schedule to be used for controlling the heat recovery unit as described above.

Heat exchanger type

This setting is used to define the type of heat exchanger being modelled. The options are:

- **1-Plate** (e.g., fixed plate) or
- **2-Rotary** (e.g., rotating cylinder or wheel).

Plate heat exchangers can be either sensible only when plates are made of a non-porous material such as aluminium, or they can also exchange latent heat when the plates are made of a porous material.

The heat exchanger type affects the modelling of frost control options and supply air outlet temperature control. For rotary heat exchangers, rotational speed is varied to control frost formation or the supply air outlet temperature. For plate exchangers, air bypass around the heat exchanger is used to obtain the desired effect.

Economiser lockout

This input denotes whether the heat exchanger unit is locked out (bypassed for plate type heat exchangers or the rotation is suspended for rotary type heat exchangers) when the air-side economiser is operating. Both the economiser and High Humidity Control activate the heat exchanger lockout as specified by this input. The input choices are **1-Yes** (meaning locked out) or **2-No**.

Sensible effectiveness at 100% heating air flow

The sensible heat exchange effectiveness at the heating condition defined in the Table above with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate specified in the previous input field. The default value for this field is 0.

Latent effectiveness at 100% heating air flow

The latent heat exchange effectiveness at the heating condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Sensible effectiveness at 75% heating air flow

The sensible heat exchange effectiveness at the heating condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. The default value for this field is 0.

Latent effectiveness at 75% heating air flow

The latent heat exchange effectiveness at the heating condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Sensible effectiveness at 100% cooling air flow

The sensible heat exchange effectiveness at the cooling condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. The default value for this setting is 0.

Latent effectiveness at 100% cooling air flow

The latent heat exchange effectiveness at the cooling condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 100% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this setting is 0.

Sensible effectiveness at 75% cooling air flow

The sensible heat exchange effectiveness at the cooling condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. The default value for this setting is 0.

Latent effectiveness at 75% cooling air flow

The latent heat exchange effectiveness at the cooling condition defined in the Operating Conditions for Defining Heat Exchanger Performance table with both the supply and exhaust air volume flow rates equal to 75% of the nominal supply air flow rate. Specify this value as 0.0 if the heat exchanger does not transfer latent energy. The default value for this field is 0.

Frost control type

There are four options for frost control:

- **1-None**,
- **2-Exhaust air recirculation**, dampers are used to direct exhaust air back into the zone through the supply side of the heat exchanger when the supply (outdoor) air inlet temperature falls below a threshold temperature (defined in the next input field). The fraction of time that exhaust air is circulated through the supply side of the heat exchanger is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time fraction (see [Rate of defrost time fraction increase](#)). When exhaust air is being re-circulated, no supply (outdoor ventilation) air is being provided through the heat exchanger unit (which may or may not be acceptable regarding ventilation for occupants).
- **3-Exhaust only** (supply air bypass): this control cycles off the supply air flow through the heat exchanger for a certain period of time while the exhaust air continues to flow through the exhaust side of the heat exchanger. The fraction of time that the supply flow through the heat exchanger is cycled off is dependent on the supply (outdoor) air inlet temperature with respect to the threshold temperature, the initial defrost time fraction, and the rate of change of defrost time fraction (see [Rate of defrost time fraction increase](#)). When implemented in real applications, provisions are usually made to avoid building depressurization when this frost control is operating (automatic or pressure-operated dampers, or a bypass air damper around the supply side of the heat exchanger). For this frost control type, it is assumed that the supply air is bypassed around the heat exchanger during frost control operation, i.e. the total supply flow is not reduced during defrost, but merely bypassed around the heat exchanger.
- **4-Minimum exhaust temperature** where the temperature of the exhaust air leaving the heat exchanger is monitored and the heat exchanger effectiveness is decreased (by slowing heat exchanger rotation or bypassing supply air around the plate exchanger) to keep the exhaust air from falling below the threshold temperature.

If a [pre-heat frost control](#) coil is specified, this setting is automatically set to **1-None** and disabled.

Threshold temperature

This numeric field defines the dry-bulb temperature of air which is used to initiate frost control (in °C or °F). The default value is 1.7°C. If **2-Exhaust air recirculation** or **3-Exhaust only** options are selected the [Frost control type](#), the threshold temperature defines the supply (outdoor) air inlet temperature below which frost control is active. For **4-Minimum exhaust temperature** frost control, heat exchanger effectiveness is controlled to keep the exhaust air outlet temperature from falling below this threshold temperature value. The appropriate threshold temperature varies with exhaust (inlet) air temperature and humidity, frost control type, heat exchanger type, and whether the heat exchanger transfers sensible energy alone or both sensible and latent energy (enthalpy). Typical threshold temperatures are provided in the table below. However, it is recommended that the user consult manufacturer's information for the specific air-to-air heat exchanger being modelled.

Frost control type	Heat exchanger type	Energy exchange	Threshold temperature
Exhaust air recirculation	Plate	Sensible-only	-1.1°C (30°F)
		Sensible + latent	-12.2°C (10°F)
	Rotary	Sensible-only	-12.2°C (10°F)
		Sensible + latent	-23.3°C (-10°F)
Exhaust only	Plate	Sensible-only	-1.1°C (30°F)
		Sensible + latent	-12.2°C (10°F)
	Rotary	Sensible-only	-12.2°C (10°F)
		Sensible + latent	-23.3°C (-10°F)
Minimum exhaust temperature	Plate	Sensible-only	1.7°C (35°F)
		Sensible + latent	1.7°C (35°F)
	Rotary	Sensible-only	1.7°C (35°F)
		Sensible + latent	1.7°C (35°F)
Preheat**	Plate	Sensible-only	-1.1°C (30°F)
		Sensible + latent	-12.2°C (10°F)
	Rotary	Sensible-only	-12.2°C (10°F)
		Sensible + latent	-23.3°C (-10°F)

Typical Threshold Temperatures

Source: Indoor Humidity Assessment Tool, U.S. Environmental Protection Agency,

** To model preheat frost control, specify frost control type as **1-None** and select a pre-heat coil for the AHU controlled to keep the air temperature above the frost threshold temperature.

Initial defrost time fraction

This is the fraction of the simulation timestep when frost control will be invoked when the threshold temperature is reached. This setting is only used for the **2-Exhaust air recirculation** and **3-Exhaust only** frost control types. The value for this setting must be ≥ 0 and ≤ 1 . The default time fraction is 0.083 (e.g., 5 min / 60 min) which is typical for Exhaust air recirculation frost control. Higher initial defrost time fractions (e.g., 0.167 = 10 min / 60 min) are typically required for Exhaust only frost control. For best results, you should obtain this information from the manufacturer.

Rate of defrost time fraction increase

This is the rate of increase in the defrost time fraction as the supply (outdoor) air inlet temperature falls below the threshold temperature. This field is only used for the **2-Exhaust air recirculation** and **3-Exhaust only** frost control types. The value for this setting must be ≥ 0 . The default value is 0.012 (e.g., 0.72 min / 60 min per degree C temperature difference) which is typical for Exhaust air recirculation frost control. Higher values (e.g. 0.024 = 1.44 min / 60 min per °C temperature difference) are typically required for Exhaust only frost control. For best results, you should obtain this information from the manufacturer.

The total defrost time fraction is determined as follows:

$$\text{Total defrost time fraction} = \text{Initial Defrost Time Fraction} + \text{Rate of Defrost Time Fraction Increase} * (T_{\text{threshold}} - T_{\text{supply air inlet}})$$

The model does not allow the total defrost time fraction to exceed 1.0 or be less than 0.

Availability schedule

This is the schedule that determines whether or not the heat recovery device is available for each timestep of the simulation. A schedule value greater than 0 (usually 1 is used) indicates that the device can be on. A value less than or equal to 0 (usually 0 is used) denotes that the device must be off.

Pre-treatment Coils

Pre-treatment heating and cooling coils, humidifiers and evaporative coolers can be included to ensure that the outside air is pre-conditioned before it enters the air handling unit. These coils are added in the same way as for other AHU coils, by navigating to the AHU object and placing coils in the outdoor air unit section of the AHU. This allows flexibility in the number and type of coils added and also in the way that they are controlled. See screenshot below.

Separate SPMs are required for pre-heat and pre-cool coils to ensure the correct off-coil conditions even if there is a temperature Setpoint Manager placed on the supply air side of the AHU.

To add SPMs to control pre-treatment coils, starting by navigating up to the supply side of the air loop. Then click on the [Add Setpoint manager](#) toolbar icon to add a SPM. See screenshot below.

Note: Only **1-Scheduled** type SPMs can be added for pre-treatment coils.

Unitary Generic AHU

The Unitary Generic AHU is intended to replace all other AHUs, although other system types are still available. This system is unique in that it can accommodate all fan and coil types whereas other AHUs are specific to the type of fan and coil available for simulation.

The generic unitary AHU incorporates an outdoor air system and a supply fan (OnOff, ConstantVolume, VariableVolume). There are also options for night cycle operation, a heat recovery system, an economiser, pre-heat and pre-cool coils and an extract fan. Additional components such as heating coils, cooling coils and humidifiers may also be added.

The Unitary AHU consists of a fan component (OnOff, ConstantVolume or VariableVolume), a cooling coil component, a heating coil component, and a reheat coil as shown in the schematic diagram above. For draw-through configurations, the fan is placed directly after the heating coil. If dehumidification control is selected, a reheat coil component is also required. If the reheat coil is present and the [Dehumidification control type](#) input is not specified as **2-Cool reheat**, the reheat coil will not be active.

In addition, the control zone and the system design operating conditions are specified in the unitary system inputs.

General

Name

This field contains the identifying name for the unitary AHU. It is read-only.

Fan type

Select the type of fan for the unitary system from the following options:

- **1-Constant volume**, used when the [Fan operating mode schedule](#) values are never 0 and the fan operates continuously.
- **2-Variable volume**, used for variable air volume systems or multi or variable-speed coils.
- **3-On/Off**, used when the fan cycles on and off with the cooling or heating coil (i.e. [Fan operating mode schedule](#) values are at times 0).

Fan placement

Select from the following options:

1-Blow through, a blow through fan where the unit consists of a fan followed by the main cooling and heating coils and supplemental heating coil. The fan “blows through” the cooling and heating coils.

2-Draw through, a draw through fan where the unit consists of the main cooling/heating coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the cooling/heating coil(s).

Fan operating mode schedule

Select a schedule that defines the supply air fan operating mode schedule. The fan operating mode may vary during the simulation based on time of day or with a change of season.

- Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (aka AUTO fan).
- Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Note: The **3-Single Zone VAV Control type** is only active when the supply air fan runs continuously, and during cycling fan operation the **1-Load** Control type model is used.

Nighttime operation

Unitary systems don't need the night cycle manager used by the standard generic AHU. Instead this functionality is achieved as follows.

1. Select the **On 24/7 Availability schedule** to allow the system to always be on.
2. Use the **Fan operating mode schedule** to switch between:
 - a. continuous fan operation for ventilation during occupied periods, and,
 - b. cycling fan for unoccupied periods to allow the system to cycle on and off as the thermostat requests, and run just enough to meet the load.

Operation

Availability schedule

Select the schedule which contains information on the availability of the unitary system to operate. A schedule value equal to 0 denotes that the unitary system must be off for that time period. A value greater than 0 denotes that the unitary system is available to operate during that time period. This schedule may be used to completely disable the unitary system as required.

Control

Control type

This setting defines the control type for the unitary system, i.e. whether it is load based or setpoint based. Select from these options:

- **1-Load** which requires a Controlling zone to be defined.
- **2- SetPoint** which requires set points at each coil outlet node. A single set point at the outlet of the system is allowed but not recommended. If setpoint control is used and the system represents a heat pump (i.e., cooling and heating coils are both DX coils) then only one of these coils may operate at a time.
- **3-Single Zone VAV** which requires two distinct fan flow rates, namely the Cooling and Heating supply air flow rate and a lower No Load Supply Air Flow Rate which is used during times of reduced cooling or heating loads. This option allows load control at low speed fan until the load exceeds available capacity or the outlet air temperature exceeds the specified limits where the fan speed is then increased. Temperature limits are identified in the input fields for [Minimum](#) and [Maximum supply air temperature](#).

Additionally, specific coil types are required for this control type. Allowed cooling coil types are: **1-Water**

and **3-DX single speed**, while the allowed heating coil types are **1-Water**, **2-Electric**, **3-Fuel** and **4-DX single speed**. If other coil types are used they are modelled using the **1-Load** based control method.

Both **1-Load** and **3-Single Zone VAV** Control types require a [Controlling zone](#) to be defined.

Controlling zone

When [Control type](#) is set to **1-Load** or **3-Single Zone VAV** you must select the zone where the thermostat controlling the unitary system is located.

Dehumidification control type

This setting allows you to select the type of dehumidification control. The following options are available:

- **1-None** - the default option where the AHU meets sensible loads only with no active dehumidification control. This option is required when Control type is set to **3-Single Zone VAV**.
- **2-Cool reheat** - where the AHU cools beyond the dry-bulb temperature set point as required to meet the high humidity setpoint.

Latent load control

This setting defines the latent load control method. Available choices are:

- **1-Sensible only**, the default option, will operate to meet only a sensible load and is also required when the **3-Single Zone VAV** Control type is selected.
- **2-Latent only** will operate to meet only a latent load
- **3-Latent with sensible** will operate to meet the latent load only if there is a sensible load.
- **4-Latent or sensible** will operate to meet either a latent or sensible load.

Supply Air Flow

Minimum supply air temperature

This numeric field contains the design operating air outlet temperature (in °C or °F) when the unitary system is cooling.

When the [Use DOAS DX cooling coil](#) checkbox is checked, this is the DX cooling coil's leaving minimum air temperature for frost control. The DX cooling coil leaving air temperature is not allowed to be lower than this minimum air temperature. The DX cooling coil frost controller adjusts or limits the desired coil outlet air setpoint temperature when the coil outlet temperature exceeds this minimum temperature limit specified. The minimum and maximum values of this input field are 0.0°C and 7.5°C respectively. The default value is 2.0°C.

When using the **3-Single Zone VAV** Control type, enter the minimum air temperature limit for reduced fan speed in cooling mode. In this case the maximum limit for the minimum supply air temperature is 20.0°C. Additionally, for the **3-Single Zone VAV** Control type, this input does not limit the minimum supply air temperature resulting from cooling coil operation at high fan speed.

Maximum supply air temperature

This numeric field contains the design operating air outlet temperature (in °C or °F) when the unitary system is heating. When using the **3-Single Zone VAV** Control type, enter the maximum air temperature limit for reduced fan speed in heating model. In this case, this input does not limit the maximum supply air temperature resulting from heating or supplemental heating coil operation at high fan speed. This field is autosizable.

Cooling supply air flow rate method

This setting defines the supply air flow method during cooling operation. Available choices are:

- **1-Supply air flow rate.**
- **2-Flow per floor area.**
- **3-Fraction of autosized cooling value.**
- **4-Flow per cooling capacity.**

For each of the choices, a corresponding air flow rate for cooling must be specified (see below). If the system does not have a cooling coil a 0 may be entered for cooling air flow rate and/or no load supply air flow rate to turn the fan off when cooling is not required.

Cooling supply air flow rate

This setting defines the supply air flow rate leaving the unitary system (in m³/s or ft³/min) when the cooling coil is operating. It is required when the Cooling supply air flow rate method is **1-Supply air flow rate**. This field is autosizable.

Cooling supply air flow rate per floor area

This setting defines the supply air flow rate per floor area leaving the unitary system (in m³/s or ft³/min) when the cooling coil is operating. It is required when the Cooling supply air flow rate method is **2-Flow per floor area**. This field is autosizable.

Cooling fraction of autosized design cooling supply air flow rate

This setting defines the fraction of autosized supply air flow rate leaving the unitary system when the cooling coil is operating. It is required when the Cooling supply air flow rate method is **3-Fraction of autosized cooling value**.

Cooling supply air flow rate per unit of capacity

This numeric field defines the supply air flow rate per unit of capacity leaving the unitary system when the cooling coil is operating. The units are or m³/s/W or (ft³/min)/(Btu/h). It is required when the Cooling supply air flow rate method is **4-Flow per cooling capacity**.

Heating supply air flow rate method

This setting defines the supply air flow method during heating operation. Available choices are:

- **1-Supply air flow rate.**
- **2-Flow per floor area.**
- **3-Fraction of autosized heating value.**
- **4-Flow per heating capacity.**

For each of the choices, a corresponding air flow rate for heating must be specified (see below). If the system does not have a heating coil a 0 may be entered for heating air flow rate and/or no load supply air flow rate to turn the fan off when heating is not required.

Heating supply air flow rate

This setting defines the supply air flow rate leaving the unitary system (in m³/s or ft³/min) when the heating coil is operating. It is required when the Heating supply air flow rate method is **1-Supply air flow rate**. This field is autosizable.

Heating supply air flow rate per floor area

This setting defines the supply air flow rate per floor area leaving the unitary system (in m³/s or ft³/min) when the heating coil is operating. It is required when the Heating supply air flow rate method is **2-Flow per floor area**. This field is autosizable.

Heating fraction of autosized design heating supply air flow rate

This setting defines the fraction of autosized supply air flow rate leaving the unitary system when the heating coil is operating. It is required when the Heating supply air flow rate method is **3-Fraction of autosized heating value**.

Heating supply air flow rate per unit of capacity

This numeric field defines the supply air flow rate per unit of capacity leaving the unitary system when the heating coil is operating. The units are or m³/s/W or (ft³/min)/(Btu/h). It is required when the Heating supply air flow rate method is **4-Flow per cooling capacity**.

No load supply air flow rate method

This setting defines the supply air flow method when neither cooling or heating is required. Available choices are:

- **1-Supply air flow rate.**
- **2-Flow per floor area.**
- **3-Fraction of autosized cooling value.**
- **4-Fraction of autosized heating value.**
- **5-Flow per cooling capacity.**
- **6-Flow per heating capacity.**

For each of these options, a corresponding air flow rate must be specified. The following "No load supply air flow rate" etc fields are also used to specify the lower air flow rate for the **3-Single Zone VAV** control method with recommendations of greater than or equal to 67% of the Cooling or Heating Supply Air Flow Rate when any DX coil is used and 50% for other coil types.

No load supply air flow rate

This numeric setting defines the supply air flow rate leaving the unitary system (in m³/s or ft³/min) when neither cooling or heating is required (i.e., when the main cooling/heating coils and supplemental heater are off but the supply air fan operates). It is only used when the unitary system operating mode is specified as continuous fan operation. It is required when the No load supply air flow rate method is **1-Supply air flow rate**.

This field is autosizable. If this field is autosized, then it is sized to the minimum of the heating and cooling lowest speed supply air flow rate. If the unitary system operating mode is specified as continuous fan operation and this value is set to zero, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

No load supply air flow rate per floor area

This numeric setting defines the supply air flow rate per floor area leaving the unitary system (in m³/s or ft³/min) when neither cooling or heating coil is operating. It is required when the No load supply air flow rate method is **2-Flow per floor area**. This field is autosizable.

No load fraction of autosized cooling supply air flow rate

This numeric field defines the fraction of autosized supply air flow rate leaving the unitary system when neither cooling or heating coil is operating. It is required when the No load supply air flow rate method is **3-Fraction of autosized cooling value**.

No load fraction of autosized heating supply air flow rate

This numeric setting defines the fraction of autosized supply air flow rate leaving the unitary system when the neither cooling or heating coil is operating. It is required when the No load supply air flow rate method is **4-Fraction of autosized heating value**.

No load supply air flow rate per unit of capacity during cooling operation

This numeric setting defines the supply air flow rate per unit of capacity leaving the unitary system when neither cooling or heating is operating. It is required when the No load supply air flow rate method is **5-Flow per cooling capacity**.

No Load Supply Air Flow Rate Per Unit of Capacity During Heating Operation

This numeric setting defines the supply air flow rate per unit of capacity leaving the unitary system when neither cooling or heating is operating. It is required when the No load supply air flow rate method is **6-Flow per heating capacity**.

Extract Fan

Include extract fan

Check the checkbox to include an extract fan.

DX Coil

DX heating coil sizing ratio

This numeric field is used to adjust heat pump heating capacity with respect to DX cooling capacity. It is used only for DX heat pump configurations (i.e., when DX cooling and DX heating coils are used).

Use DOAS DX cooling coil

Important Note: In DesignBuilder v2025.1, this option should be left unchecked due to a bug in EnergyPlus v23.1: [#11378](#).

This input field enables DX Cooling coils to be used for 100% outdoor air dedicated outdoor air system applications.

When this option is checked, the DX coil is used as 100% outdoor DX coil.

When it is unchecked, the DX coil is used as regular DX coil.

This option is not available when the **3-Single Zone VAV Control type** is selected.

Compressor

Maximum cycling rate

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values for Maximum cycling rate are shown below(Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Heat Pump

Heat pump time constant

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown in the table below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Heat pump fan delay time

This numeric field contains the time delay for the heat pump supply air fan to shut off after the compressor cycles off in seconds. This value can be obtained from the manufacturer or the heat pump catalog. Enter a value of zero when the heat pump's fan operating mode is continuous. Suggested value is 60 seconds.

On-Cycle And Off-Cycle Power Use

Fraction of on-cycle power use

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are shown in the table below. (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Ancillary on-cycle electric power

This field defines ancillary electrical power (W) consumed during the on-cycle period (i.e., when the cooling or heating coil is operating). The model assumes that this ancillary power does not contribute to heating the supply air.

Ancillary off-cycle electric power

This field defines ancillary electrical power (W) consumed during the off-cycle period (i.e., when the cooling and heating coil are not operating). The model assumes that this ancillary power does not contribute to heating the supply air.

Supplemental Heater

Maximum outdoor dry-bulb temperature for supplemental heater operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21°C.

Mixed Mode Zone Equipment

You can set up Mixed mode controls for the AHU to model optimal interaction between the natural ventilation system (Scheduled or Calculated) and the AHU.

Refer to the main HVAC tab [Mixed Mode](#) section for details on the options available.

Note: If mixed mode is activated here on the AHU dialog, then any mixed mode settings for connected zones on the HVAC tab will be overridden by these mixed mode settings.

Outdoor Air System

See [Outdoor air system description for Generic AHU](#)

Unitary Heat Cool AHU

The unitary heat cool AHU incorporates an EnergyPlus unitary heat cool component, an outdoor air system (see Air Handling Unit Outdoor Air System), optional night cycle operation, an optional heat recovery system (see Heat Recovery), optional pre-heat and pre-cool coils and an optional extract fan. The unitary heat cool component itself comprises a supply fan, a DX cooling coil component and an electric heating coil component. If dehumidification control is selected, an electric reheat coil is automatically included.

Note: The Unitary Heat Cool AHU can only be added as part of a [Unitary Heat Cool Air loop](#) .

A detailed description of how Unitary air loops work is provided in the [EnergyPlus Engineering Reference](#).

General

Name

This is the name that you assign to the AHU which should be unique. If the supplied name is not unique, the software will automatically append a backslash and integer to ensure that there are no duplicate names.

Operation

Availability schedule

This schedule contains information on the availability of the AHU for operation. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

When this unit is unavailable (schedule values of 0) then all equipment contained within this AHU will also be switched off.

Supply Air Temperature

Maximum supply air temperature

This is the design operating air outlet temperature (in °C or °F) when the unitary system is heating.

Supply Air Flow Rates

Design air flow rate

This is the air loop primary air design volumetric flow rate (in m³/s or ft³/min). This setting is auto-sizeable.

Cooling operation air flow rate

This setting defines the supply air flow rate leaving the heat pump (in m³/s or ft³/min) when the DX cooling coil is operating. Values must be greater than 0 or this field is auto-sizeable.

Heating operation air flow rate

This setting defines the supply air flow rate leaving the heat pump (in m³/s or ft³/min) when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is auto-sizeable.

Supply air flow rate when no cooling or heating is needed

This setting defines the supply air flow rate leaving the heat pump (in m³/s or ft³/min) when neither cooling nor heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This setting is only used when the heat pump operating mode is specified as continuous fan operation (see Supply Air Fan Operating Mode Schedule). Values must be greater than or equal to zero, or this field is auto-sizeable. If the heat pump operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Supply Fan

Fan type

Two fan types are available for selection in this AHU:

- **1-Constant volume** where the fan delivers a constant flow rate through the unit regardless of whether the unit is heating, cooling and/or providing fresh air. Constant volume fans don't use the [Supply air fan operating mode schedule](#) (below). When this option is selected an [extract fan](#) can optionally also be included in the AHU.
- **3-On/Off** where the [Supply air fan operating mode schedule](#) (below) determines the flow regime. In this case an extract fan cannot be selected.

Supply fan placement

There are two options:

- **1-Blow through** where the supply air fan is before the DX cooling/heating coil.
- **2-Draw through** where the supply air fan is after the DX cooling/heating coil.

Supply air fan operating mode schedule

The supply air fan operating mode schedule can only be selected for On/Off fan types. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule

values of 0 indicate that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (sometimes referred to as an "AUTO" fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

The default schedule is "Fan operation mode - Continuous" with a constant value of 1, i.e. that the supply fan runs continuously while the heating or cooling coil cycles to meet the load at all times. To obtain the AUTO fan configuration, select the "Fan operation mode - Cycling" schedule which has a constant value of 0.

Extract Fan

Include extract fan

An extract fan is included within all AHUs by default. This setting may be used to remove the extract fan from the AHU.

Note: This option is only available for **Constant volume** fan types. **On/Off** fans do not allow an extract fan to be included in the AHU and when this fan type is selected the **Include extract fan** check box will be disabled.

Thermostat Location

Controlling zone or thermostat location

While the unitary heat cool AHU may be configured to serve multiple zones, system operation is controlled by a thermostat located in a single "control" zone. Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone supplied by the AHU where the thermostat controlling the unitary heat cool AHU is located.

Dehumidification

Dehumidification control type

There are two options for dehumidification control:

1-None - meet sensible load only, no active de-humidification control;

2-Cool Reheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint.

Note: If **2-Cool Reheat** is used, a humidistat must be defined in one of the zones supplied by the AHU.

More information on controlling humidity is available in the [Humidity control](#) section.

Night Cycle

See [Night cycle description for Generic AHU](#)

Mixed Mode

You can set up Mixed mode controls for the AHU to model optimal interaction between the natural ventilation system (Scheduled or Calculated) and the AHU.

Refer to the main HVAC tab [Mixed Mode](#) section for details on the available options.

Outdoor Air System

See [Outdoor air system description for Generic AHU](#)

Unitary Air To Air Heat Pump AHU

The unitary air-to-air heat pump AHU incorporates an EnergyPlus unitary air-to-air heat pump component, an outdoor air system, optional night cycle operation, an optional heat recovery system, optional pre-heat and pre-cool coils and an optional extract fan. The unitary air-to-air heat pump component itself comprises a supply fan, a DX cooling coil component, a DX heating coil component, and an electric, hot water or fuel supplementary heating coil component.

Tip: The Unitary Air to Air Heat Pump AHU can be used to model ASHRAE 90.1 Appendix G System 4 PSZ-HP.

Note: The Unitary Air to Air Heat Pump AHU can only be added as part of a [Unitary Air to Air Heat Pump Air loop](#).

A detailed description of how Unitary air loops work is provided in the [EnergyPlus Engineering Reference](#).

General

Name

This is the name that you assign to the AHU which should be unique. If the supplied name is not unique, the software will automatically append a backslash and integer to ensure that there are no duplicate names.

Operation

Availability schedule

This schedule contains information on the availability of the AHU for operation. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

When this unit is unavailable (schedule values of 0) then all equipment contained within this AHU will also be switched off.

Supply Air Flow Rates

Cooling operation air flow rate

This setting defines the supply air flow rate leaving the heat pump (in m³/s or ft³/min) when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Heating operation air flow rate

This setting defines the supply air flow rate leaving the heat pump (in m³/s or ft³/min) when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is auto-sizable.

Supply air flow rate when no cooling or heating is needed

This setting defines the supply air flow rate leaving the heat pump (in m³/s or ft³/min) when neither cooling nor heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This setting is only used when the heat pump operating mode is specified as continuous fan operation (see Supply Air Fan Operating Mode Schedule). Values must be greater than or equal to zero, or this field is auto-sizable. If the heat pump operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Supply Fan

Fan type

Two fan types are available for selection in this AHU:

- **1-Constant volume** where the fan delivers a constant flow rate through the unit regardless of whether the unit is heating, cooling and/or providing fresh air. Constant volume fans don't use the [Supply air fan operating mode schedule](#) (below). When this option is selected an [extract fan](#) can optionally also be included in the AHU.
- **3-On/Off** where the [Supply air fan operating mode schedule](#) (below) determines the flow regime. In this case an extract fan cannot be selected.

Supply fan placement

There are two options:

- **1-Blow through** where the supply air fan is before the DX cooling/heating coil and the supplementary heating coil.
- **2-Draw through** where the supply air fan is between the DX cooling/heating coil and the supplementary heating coil.

Supply air fan operating mode schedule

The supply air fan operating mode schedule can only be selected for On/Off fan types. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule

values of 0 indicate that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (sometimes referred to as an "AUTO" fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

The default schedule is "Fan operation mode - Continuous" with a constant value of 1, i.e. that the supply fan runs continuously while the heating or cooling coil cycles to meet the load at all times. To obtain the AUTO fan configuration, select the "Fan operation mode - Cycling" schedule which has a constant value of 0.

Extract Fan

Include extract fan

An extract fan is included within all AHUs by default. This setting may be used to remove the extract fan from the AHU.

Note: This option is only available for **Constant volume** fan types. **On/Off** fans do not allow an extract fan to be included in the AHU and when this fan type is selected the **Include extract fan** check box will be disabled.

Thermostat Location

Controlling zone or thermostat location

While the heat pump may be configured to serve multiple zones, system operation is controlled by a thermostat located in a single "control" zone. Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone supplied by the AHU where the thermostat controlling the heat pump is located.

Dehumidification

Dehumidification control type

There are two options for dehumidification control:

1-None - meet sensible load only, no active de-humidification control;

2-Cool Reheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint.

Note: If the **2-Cool Reheat** option is selected then some further settings are also required:

a) a **humidistat** must be defined on the HVAC zone dialog of the control zone supplied by the AHU.

b) DesignBuilder v6 requires that a SPM be added to the outlet of the Unitary HP AirToAir AHU. Valid SPM options are: **5-Multi-zone maximum humidity average**, **7-Multi-zone humidity maximum** and **9-Single-zone humidity maximum**.

Tip: To provide humidification, a humidifier should be added to the AHU and a setpoint manager added downstream of the AHU with one of the "minimum humidity" control options.

Supplemental Heater

If the heat pump's DX heating coil output at full load is insufficient to meet the entire heating load, the part load ratio is set equal to 1.0 (compressor and fan are not cycling) and the remaining heating load is passed to the supplemental heating coil. If the outdoor air temperature is below the minimum outdoor air temperature for

compressor operation, the compressor is turned off and the entire heating load is passed to the supplemental gas or electric heating coil.

Maximum supply air temperature from supplemental heater

This setting defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil.

Maximum outdoor dry-bulb temperature for supplemental heater operation

This setting defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21°C.

Night Cycle

See [Night cycle description for Generic AHU](#)

Mixed Mode

You can set up Mixed mode controls for the AHU to model optimal interaction between the natural ventilation system (Scheduled or Calculated) and the AHU.

Refer to the main HVAC tab [Mixed Mode](#) section for details on the available options.

Outdoor Air System

See [Outdoor air system description for Generic AHU](#)

Unitary Water To Air Heat Pump AHU

The unitary water-to-air heat pump AHU incorporates an EnergyPlus unitary water-to-air heat pump component, an outdoor air system, optional night cycle operation, an optional heat recovery system, optional pre-heat and pre-cool coils and an optional extract fan. The unitary water-to-air heat pump component itself comprises a [supply fan](#), a [water-to-air heat pump cooling coil](#) component, a [water-to-air heat pump heating coil](#) component, and an electric, hot water or fuel supplementary heating coil component.

The unitary water-to-air heat pump is similar to the [unitary air-to-air heat pump](#) except water is used on the source side, connected to a condenser loop with a [heat exchanger](#) (ground heat exchanger or other type) or a plant loop with a heating source such as a boiler and a cooling source such as a chiller or cooling tower.

Note: The Unitary Water to Air Heat Pump AHU can only be added as part of a [Unitary Water to Air Heat Pump Air loop](#).

A detailed description of how Unitary air loops work is provided in the [EnergyPlus Engineering Reference](#).

General

Name

This is the name that you assign to the AHU which should be unique. If the supplied name is not unique, the software will automatically append a backslash and integer to ensure that there are no duplicate names.

Operation

Availability schedule

This schedule contains information on the availability of the AHU for operation. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

When this unit is unavailable (schedule values of 0) then all equipment contained within this AHU will also be switched off.

Supply Air Flow Rates

Supply air flow rate

This setting defines the design supply air flow rate through the heat pump (in m³/s or ft³/min). This volume flow rate is only used when the cooling and heating coil object type is Parameter Estimation. Although a value greater than 0 is required (input cannot be blank or 0), this input is not used for the Equation Fit coil model. Instead, the supply air flow rate is determined by the input in the corresponding Equation Fit coil objects.

Supply Fan

Supply fan placement

There are two options:

- **1-Blow through** where the supply air fan is before the DX cooling/heating coil and the supplementary heating coil.
- **2-Draw through** where the supply air fan is between the DX cooling/heating coil and the supplementary heating coil.

Supply air fan operating mode schedule

The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 indicate that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (sometimes referred to as an "AUTO" fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

The default schedule is "Fan operation mode - Continuous" with a constant value of 1, i.e. that the supply fan runs continuously while the heating or cooling coil cycles to meet the load at all times. To obtain the AUTO fan configuration, select the "Fan operation mode - Cycling" schedule which has a constant value of 0.

Supply fan delay time

This is the time delay for the heat pump supply air fan to shut off after the compressor cycles off in seconds. This value can be obtained from the manufacturer or the heat pump catalog. Enter a value of zero when the heat pump's fan operating mode is continuous. The suggested value is 60 seconds.

Thermostat Location

Controlling zone or thermostat location

While the heat pump may be configured to serve multiple zones, system operation is controlled by a thermostat located in a single "control" zone. Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone supplied by the AHU where the thermostat controlling the heat pump is located.

On Cycle Power Use

Fraction on cycle power use

Enter the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans etc. Some suggested value values are provided below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Dehumidification

Dehumidification control type

There are two options for dehumidification control:

1-None - meet sensible load only, no active de-humidification control;

2-Cool Reheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint.

Note: If **2-Cool Reheat** is used, a humidistat must be defined in one of the zones supplied by the AHU.

Tip: To provide humidification, a humidifier should be added to the AHU and a [setpoint manager](#) added downstream of the AHU with one of the "minimum humidity" control options.

Cooling Coil

Cooling coil time constant

Enter the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Compressor

Maximum cycling rate

Enter the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Supplemental Heater

If the heat pump's DX heating coil output at full load is insufficient to meet the entire heating load, the part load ratio is set equal to 1.0 (compressor and fan are not cycling) and the remaining heating load is passed to the supplemental heating coil. If the outdoor air temperature is below the minimum outdoor air temperature for compressor operation, the compressor is turned off and the entire heating load is passed to the supplemental gas or electric heating coil.

Maximum supply air temperature from supplemental heater

This setting defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil.

Maximum outdoor dry-bulb temperature for supplemental heater operation

This setting defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21°C.

Coil Water Flow Rate

Heat pump coil water flow mode

This data specifies the way in which water flow through the heat pump coils will be modelled. It is only used when WatertoAirHeatPump:EquationFit coils are used. There are three options:

- **1-Cycling** which varies water flow through the coil based on the heat pump Part Load Ratio. This control method is appropriate for modelling heat pumps that are outfitted with a solenoid valve which allows water to flow through the coil only when the compressor is active. This is the default setting.
- **2-Constant** which provides a constant water flow regardless of heat pump operation. Remember that EnergyPlus has two coils (a heating coil and a cooling coil) to approximate the operation of one coil that can operate in either heating mode or cooling mode. Therefore, when the water flow mode is constant, there will be full flow through either the heating coil or the cooling coil, but not both at the same time.
- **3-Constant on demand** which provides full flow through the coil whenever there is a load. When there is no load, there is zero flow through the coil.

Night Cycle

See [Night cycle description for Generic AHU](#)

Mixed Mode

You can set up Mixed mode controls for the AHU to model optimal interaction between the natural ventilation system (Scheduled or Calculated) and the AHU.

Refer to the main HVAC tab [Mixed Mode](#) section for details on the available options.

Advanced

Cooling convergence

This numeric value allows the user to determine how close the air side has to be controlled. The lower the value of convergence the better the control of air side conditions and the less the zone temperature fluctuates. However in a poorly designed system, a lower convergence might result in warnings which are caused due to the iteration limit for run time fraction calculation is limited to 20.

Heating convergence

This numeric value allows the user to determine how close the air side has to be controlled. The lower the value of convergence the better the control of air side conditions and the less the zone temperature fluctuates. However in a poorly designed system, a lower convergence might result in warnings which are caused due to the iteration limit for run time fraction calculation is limited to 20.

Outdoor Air System

See [Outdoor air system description for Generic AHU](#)

DOAS AHU

The Dedicated Outdoor Air System (DOAS) AHU is a central dedicated outdoor unit that typically delivers outdoor air to multiple air loops. The amount of delivered outdoor air is based on a sum of outdoor air flow rate demands from the downstream AHU outdoor air nodes.

Central DOAS systems can also pre-treat outdoor air before distributing it the connected AHUs, with given precool and preheat air conditions. This is achieved by adding components such as heating and cooling coils and humidifiers to the DOAS AHU in the same way as for standard AHUs.

One restriction with DOAS AHUs is that the fan type must be of the **4-System model** type.

The DOAS AHU dialog currently has 2 fields, only one of which is user-definable. These are described below.

General

Name

This is a unique, system-defined, non-editable name assigned to the AHU.

Operation

Availability schedule

This schedule contains information on the availability of the DOAS AHU for operation. A schedule value greater than 0 (1 is usually used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

When this unit is unavailable (schedule values of 0) then any equipment contained within this AHU will also be switched off.

Connecting To Standard AHUs

To allow a DOAS AHU to be connected to standard AHUs, it is necessary to enable the DOAS connections in the standard AHUs.

Plenum Data

Supply and Extract plenums are HVAC components much like Splitters and Mixers but they can be associated with a building zone which is used as the supply or extract plenum.

The only item of data required for an HVAC plenum is the name of the associated building zone.

Zone name

If no zone has previously been allocated to the plenum, click on the ellipsis button adjacent to the <Select zone> text to bring up a zone selection control. Only zones that have not already been associated with zone groups or other plenums are available for selection.

See also [Add Supply/Return Plenum Tool](#)

Fans

The following fan types are available when using Detailed HVAC:

- [Fan - Constant Volume](#)
- [Fan - Variable Volume](#)
- [Fan - On/Off](#)
- [Fan - Zone Exhaust](#)

Fan - Constant Volume

Fan:ConstantVolume

Used in:

- Air Handling Unit (Constant Volume)
- Fan Coil Unit

- PTAC,
- PTHP,
- Unitary Heat Cool,
- Unitary Heat Pump

This object models a constant air volume fan that is intended to operate continuously based on a time schedule. This fan will not cycle on and off based on cooling/heating load or other control signals.

General

Name

A unique auto-assigned name for the Fan. Any reference to this fan by another object will use this name.

Type

The type of the constant volume fan is fixed as:

- **2-Constant volume**

Note: To change from constant volume to variable volume you must open the parent [AHU](#) dialog and change the AHU [Fan type](#) to **2-Variable volume**. To allow the AHU Fan type to be edited you must first disconnect the demand side of the air loop from all zone ADUs by deleting connecting branches.

Fan total efficiency

This is the overall efficiency of the fan, i.e. the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is the power delivered to the air divided by the shaft power. The power delivered to the air is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This efficiency must be between 0 and 1.

Pressure rise

The pressure rise (in Pascals or inH₂O) at full flow and standard (sea level) conditions (20°C and 101325 Pa).

The required pressure rise across an AHU fan is dependent on the duct network supplied by the AHU. For example, if a duct network was sized using a constant pressure loss of 1 Pa/m and the index run of the network (route of highest pressure drop) was say 300 m and the fitting losses were say an additional 20%, the required pressure rise across the fan would be 300 x 1 x 1.2= 360 Pa.

End-use subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Central System", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

Flow Rates

Maximum flow rate

The full load air volumetric flow rate (m³/sec or ft³/min) at standard temperature and pressure (dry air at 20°C dry-bulb). EnergyPlus uses local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)**5.2559$$

where p=pressure in Pa and Z=altitude in m

Motor

Motor efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Motor in airstream fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Operation

Availability schedule

Select the [Schedule](#) that defines whether the fan can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the fan is off.

Algorithm

The way that fan and motor efficiency values affect the condition of the air at the fan outlet is given by the following equations:

$$\begin{aligned}Q_{\text{tot}} &= m \cdot \delta P / (e_{\text{tot}} \cdot \rho_{\text{air}}) \\Q_{\text{shaft}} &= e_{\text{motor}} \cdot Q_{\text{tot}} \\Q_{\text{toair}} &= Q_{\text{shaft}} + (Q_{\text{tot}} - Q_{\text{shaft}}) \cdot f_{\text{motortoair}} \\h_{\text{out}} &= h_{\text{in}} + Q_{\text{toair}} / m \\w_{\text{out}} &= w_{\text{in}} \\T_{\text{out}} &= \text{PsyTdbFnHW}(h_{\text{out}}, w_{\text{out}})\end{aligned}$$

Nomenclature:

$f_{\text{motortoair}}$ is the fraction of motor heat generated passed into the air stream
 Q_{tot} is fan power in W
 m is mass flow in kg/s
 δP is the design pressure increase
 e_{tot} is fan total efficiency
 e_{motor} is the motor efficiency
 ρ_{air} is air density at standard conditions (kg/m³)
 Q_{shaft} is the fan shaft power in W
 Q_{toair} is the power entering the air in W
 $h_{\text{out}}, h_{\text{in}}$ are the outlet and inlet specific enthalpies in J/kg
 $w_{\text{out}}, w_{\text{in}}$ are the inlet and outlet air stream humidity ratios
PsyTdbFnHW is the EnergyPlus psychrometric routine relating enthalpy and humidity ratio to temperature.

Fan - Constant Volume Outputs

HVAC, Average, Fan Electric Power[W]
HVAC, Average, Fan Delta Temp[C]
HVAC, Sum, Fan Electric Consumption[J]

Fan Electric Power [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

Fan Delta Temp [C]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) (in °C or °F) for the timestep being reported.

Fan Electric Consumption [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= Fans, Group Key= System (ref. Report Meter).

Fan - Variable Volume

Fan:VariableVolume

Used in:

- **Air Handling Unit (Variable Volume)**

General

Name

A unique auto-generated name for the fan. Any reference to this fan by another object will use this name.

Type

The type of the variable volume fan is fixed as:

- **2-Variable volume**

Note: To change from variable volume to constant volume you must open the parent [AHU](#) dialog and change the AHU [Fan type](#) to **1-Constant volume**. To allow the AHU Fan type to be edited you must first disconnect the demand side of the air loop from all zone ADUs by deleting connecting branches.

Fan total efficiency

This is the overall efficiency of the fan, i.e. the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is the power delivered to the air divided by the shaft power. The power delivered to the air is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This efficiency must be between 0 and 1.

Pressure rise

The pressure rise (in Pascals or inH2O) at full flow and standard (sea level) conditions (20°C and 101325 Pa).

The required pressure rise across an AHU fan is dependent on the duct network supplied by the AHU. For example, if a duct network was sized using a constant pressure loss of 1 Pa/m and the index run of the network (route of highest pressure drop) was say 300 m and the fitting losses were say an additional 20%, the required pressure rise across the fan would be $300 \times 1 \times 1.2 = 360$ Pa.

End-use subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Central System", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

Flow Rates

Fan minimum flow rate input method for fan power

This field is a key/choice field that tells which of the next two fields is filled and is descriptive of how the minimum flow rate is specified for calculating the fan power. The key/choices are:

- **1-Fraction** where the fan power will be calculated using the value specified in the **Minimum flow fraction for fan power** below.
- **2-Fixed flow rate** where the fan power is calculated using the value specified in the **Minimum air flow rate for fan power** below.

Minimum flow fraction for fan power

The minimum air volumetric flow rate for fan power, specified as a fraction of maximum system air flow rate. Must be between 0 and 1. Note that this field is only used to calculate the fan power. This field does not enforce the system air flow rate during simulation.

Minimum air flow rate for fan power

The minimum air volumetric flow rate for fan power, specified as a constant minimum air flow rate (m3/sec or ft3/min). Note that this field is only used to calculate the fan power. This field does not enforce the system air flow rate during simulation.

Maximum flow rate

The full load air volumetric flow rate (m3/sec or ft3/min) at standard temperature and pressure (dry air at 20°C dry-bulb). The program does use local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)^{5.2559}$$

where p=pressure in Pa and Z=altitude in m

Minimum flow rate

The minimum air volumetric flow rate (m3/sec or ft3/min) for the fan at standard temperature and pressure (see Maximum Flow Rate field above for details).

Motor

Motor efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Motor in airstream fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Fan Coefficients

Fan coefficient data under this header provides the coefficients C2 to C5 in the fourth order polynomial curve giving the fraction of full load power (PLF) as a function of flow fraction (FF). Flow fraction is the air mass flow rate divided by the maximum air mass flow rate.

$$PLF = C_1 + C_2 \cdot FF + C_3 \cdot FF^2 + C_4 \cdot FF^3 + C_5 \cdot FF^4$$

Fan coefficient 1

The constant coefficient C_1 in the above curve

Fan coefficient 2

The linear coefficient C_2 in the above curve

Fan coefficient 3

The quadratic coefficient C_3 in the above curve

Fan coefficient 4

The cubic coefficient C_4 in the above curve

Fan Coefficient 5

The coefficient C_5 in the above curve

Operation

Availability schedule

[Schedule](#) that defines whether the fan can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the fan is off.

Algorithm

The algorithm used to calculate energy consumption and air outlet conditions in variable flow fans are as follows.

$$\begin{aligned} f_{\text{flow}} &= m / m_{\text{max}} \\ f_{\text{pl}} &= c_1 + c_2 \cdot f_{\text{flow}} + c_3 \cdot f_{\text{flow}}^2 + c_4 \cdot f_{\text{flow}}^3 + c_5 \cdot f_{\text{flow}}^4 \\ Q_{\text{tot}} &= f_{\text{pl}} \cdot m \cdot \delta P / (e_{\text{tot}} \cdot \rho_{\text{air}}) \\ Q_{\text{shaft}} &= e_{\text{motor}} \cdot Q_{\text{tot}} \\ Q_{\text{toair}} &= Q_{\text{shaft}} + (Q_{\text{tot}} - Q_{\text{shaft}}) \cdot f_{\text{motortair}} \\ h_{\text{out}} &= h_{\text{in}} + Q_{\text{toair}} / m \\ w_{\text{out}} &= w_{\text{in}} \\ T_{\text{out}} &= \text{PsyTdbFnHW}(h_{\text{out}}, w_{\text{out}}) \end{aligned}$$

Nomenclature:

f_{flow} is the flow fraction of design or maximum flow
 $f_{\text{motortair}}$ is the fraction of motor heat generated passed into the air stream
 f_{pl} is the part load factor
 Q_{tot} is fan power in W
 m is mass flow in kg/s
 δP is the design pressure increase
 e_{tot} is fan total efficiency
 e_{motor} is the motor efficiency
 ρ_{air} is air density at standard conditions (kg/m³)
 Q_{shaft} is the fan shaft power in W
 Q_{toair} is the power entering the air in W
 $h_{\text{out}}, h_{\text{in}}$ are the outlet and inlet specific enthalpies in J/kg
 $w_{\text{out}}, w_{\text{in}}$ are the inlet and outlet air stream humidity ratios

PsyTdbFnHW is the EnergyPlus psychrometric routine relating enthalpy and humidity ratio to temperature.

Fan - Variable Volume Outputs

HVAC,Average,Fan Electric Power[W]
HVAC,Average,Fan Delta Temp[C]
HVAC,Sum,Fan Electric Consumption[J]

Fan Electric Power [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

Fan Delta Temp [C]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) (in °C or °F) for the timestep being reported.

Fan Electric Consumption [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= Fans, Group Key= System (ref. Report Meter).

Fan - On/Off

Used in:

- Fan Coil Unit
- PTAC,
- PTHP,
- Unitary Heat Cool,
- Unitary Heat Pump

The On/off fan models a constant air volume fan that is intended to cycle on and off in tandem with a cooling or heating system (i.e., AUTO fan control mode). The fan can also operate continuously like a [Constant volume fan](#). If modelling continuous operation and this object is used as part of a system that utilizes Coil:Heating:Gas, Coil:Cooling:DX:SingleSpeed or Coil:Heating:DX:SingleSpeed, the user should confirm proper air flow rates (coil and fan max load fraction is less than or equal to 1 for all values of coil part-load ratio).

Multi-speed fan operation can also be modelled when the On/off fan is included as part of a compound object that allows multiple fan speeds (e.g., Unitary Heat Cool, PTAC, etc.). In this case, the ratio of the compound object air flow rate to the fan's maximum air flow rate is used to determine the power at alternate fan speeds. The input for Fan Power Ratio Function of Speed Ratio Curve Name must be entered to model multi-speed fan operation. An optional fan total efficiency ratio curve is also available to model efficiency differences at alternate fan speeds.

Name

A unique system assigned name for an instance of an On/off fan. Any reference to this fan by another object will use this name.

Fan total efficiency

This is the overall efficiency of the fan, i.e. the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power

delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is the power delivered to the air divided by the shaft power. The power delivered to the air is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This efficiency must be between 0 and 1.

Pressure rise

The pressure rise (in Pascals or inH2O) at full flow and standard (sea level) conditions (20°C and 101325 Pa).

The required pressure rise across an AHU fan is dependent on the duct network supplied by the AHU. For example, if a duct network was sized using a constant pressure loss of 1 Pa/m and the index run of the network (route of highest pressure drop) was say 300 m and the fitting losses were say an additional 20%, the required pressure rise across the fan would be $300 \times 1 \times 1.2 = 360$ Pa.

End-use subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Central System", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

Maximum flow rate

The full load air volumetric flow rate (m3/sec or ft3/min) at standard temperature and pressure (dry air at 20°C dry-bulb). EnergyPlus uses local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z)^{5.2559}$$

where p=pressure in Pa and Z=altitude in m

Motor efficiency

The shaft power divided by the electrical power consumed. Must be between 0 and 1.

Motor in airstream fraction

The fraction of the motor heat that is added to the air stream. A value of 0 means that the motor is completely outside the air stream. A value of 1 means that all of the motor heat loss will go into the air stream and act to cause a temperature rise. Must be between 0 and 1.

Fan power ratio function of speed ratio curve

Select an [Exponent Performance curve](#). This curve is used to simulate multi-speed fan motors, representing the ratio of actual fan power to rated fan power when a change in fan speed occurs.

Fan efficiency ratio function of speed ratio curve

Enter the name of a [Quadratic](#) or [Cubic](#) Performance curve. This curve is used to simulate multi-speed fan motors, representing the ratio of actual fan total efficiency to rated fan total efficiency when a change in fan speed occurs.

Operation

Availability schedule

Select the [Schedule](#) that defines whether the fan can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the fan is off.

Algorithm

The on/off fan model is similar to the simple constant volume fan model with the exception that the on/off fan may cycle on and off during a simulation time step. The cycling rate of the fan is known as the run time fraction. The calculation of run time fraction accounts for the part-load losses of other equipment used in the HVAC system. A part-load factor (a.k.a. part-load ratio) is first calculated for the fan as the ratio of the actual operating mass flow rate to the maximum fan mass flow rate. The run time fraction is then calculated as the part-load factor divided by the part-load fraction. The part-load fraction is determined by other HVAC equipment in the simulation.

$$f_{\text{flow}} = m / m_{\text{max}}$$
$$\text{RTF} = f_{\text{flow}} / \text{PLF}$$

The total fan power is then calculated as the maximum fan power multiplied by the run time fraction.

$$Q_{\text{tot}} = \text{RTF} \cdot [m \cdot \delta P / (e_{\text{tot}} \cdot \rho_{\text{air}})]$$
$$Q_{\text{shaft}} = e_{\text{motor}} \cdot Q_{\text{tot}}$$
$$Q_{\text{toair}} = Q_{\text{shaft}} + (Q_{\text{tot}} - Q_{\text{shaft}}) \cdot f_{\text{motortoair}}$$
$$h_{\text{out}} = h_{\text{in}} + Q_{\text{toair}} / m$$
$$w_{\text{out}} = w_{\text{in}}$$
$$T_{\text{out}} = \text{PsyTdbFnHW}(h_{\text{out}}, w_{\text{out}})$$

Nomenclature:

f_{flow} is the flow fraction or part load ratio
 $f_{\text{motortoair}}$ is the fraction of motor heat generated passed into the air stream
 Q_{tot} is fan power in W
 m is mass flow in kg/s
 m_{max} is the maximum or design mass flow in kg/s
RTF is runtime fraction
PLF is part load factor
 δP is the design pressure increase
 e_{tot} is fan total efficiency
 e_{motor} is the motor efficiency
 ρ_{air} is air density at standard conditions (kg/m³)
 Q_{shaft} is the fan shaft power in W
 Q_{toair} is the power entering the air in W
 $h_{\text{out}}, h_{\text{in}}$ are the outlet and inlet specific enthalpies in J/kg
 $w_{\text{out}}, w_{\text{in}}$ are the inlet and outlet air stream humidity ratios
PsyTdbFnHW is the EnergyPlus psychrometric routine relating enthalpy and humidity ratio to temperature.

Fan - On/Off Outputs

HVAC, Average, Fan Electric Power[W]
HVAC, Average, Fan Delta Temp[C]
HVAC, Sum, Fan Electric Consumption[J]
HVAC, Average, On/Off Fan Runtime Fraction

Fan Electric Power [W]

This output field contains the average electricity consumption rate for the fan in Watts for the timestep being reported.

Fan Delta Temp [C]

This output field contains the average rise in air temperature across the fan (outlet air temperature minus inlet air temperature) (in °C or °F) for the timestep being reported.

Fan Electric Consumption [J]

This output field contains the electricity consumption of the fan in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= Fans, Group Key= System (ref. Report Meter).

On/Off Fan Runtime Fraction

This output field contains the fraction of time that this fan operated for the timestep being reported

Fan - System Model

The System Model fan models fans of various types using a relatively simple engineering model. It can be used in variable air volume, constant volume, on-off cycling, two-speed, or multi-speed applications. It was designed as a replacement for all of the other fan types: [Constant Volume](#), [On/Off](#), and [Variable Volume](#).

The electric power consumed by the fan can be directly input or autosized using one of three optional methods. For fans that can vary the volume flow rate the performance can be described using a separate performance curve.

General

Name

A unique auto-generated name for the fan. Any reference to this fan by another object will use this name.

Type

The type of the System Model fan is fixed as:

- **4-System model**

Design pressure rise

This is the total system design pressure rise experienced by the fan (in Pascals or inH₂O) at full flow rate and altitude-adjusted standard density of dry air at 20°C drybulb.

Electric Power

Design electric power consumption method

Select from:

- **1-Autosize**, where EnergyPlus will autosize the [Electric power per unit flow rate](#) using one of the methods listed below under [Design power sizing method](#).
- **2-Manual input**, where the [Design electric power consumption](#) is entered manually in the setting below.

Design electric power consumption

This setting is available when the [Design electric power consumption method](#) is set to **2-Manual input**. It is the electric power consumption at the full [Maximum flow rate](#) and [Pressure rise](#) (in W). The value entered in this field is used to determine the fan efficiency.

Design power sizing method

This setting is used when the [Design electric power consumption method](#) is set to **1-Autosize** to select how the fan's Design electric power consumption is sized. There are three choices:

- **1-Power per flow**, where the value entered for [Electric power per unit flow rate](#) is used to size the Design electric power consumption. This method is useful during early-phase design modelling when little information is available for determining the Design pressure rise. Although the pressure rise is not

used to size the [Design electric power consumption](#) it is still used to determine the heat added to the air stream as a result of the work done by the fan.

- **2-Power per flow per pressure**, where the value entered for [Electric power per unit flow rate per unit pressure](#) is used to size the [Design electric power consumption](#). This method takes into account the Design Pressure Rise when sizing the Design Electric Power Consumption.
- **3-Total efficiency and pressure**, where the values entered for [Fan total efficiency](#) and [Design pressure rise](#) are used to size the power.

Electric power per unit flow rate

This setting is used when the [Design electric power consumption method](#) is set to **1-Autosize** and the [Design power sizing method](#) is set to **1-Power per flow**. This value has units of W/(m³/s) and is used to scale the [Design electric power consumption](#) directly from the [Maximum flow rate](#). It is defined such that

Design electric power consumption = (Electric power per unit flow rate) * (Maximum flow rate).

Electric power per unit flow rate per unit pressure

This setting is used when the [Design electric power consumption method](#) is set to **1-Autosize** and the [Design power sizing method](#) is set to **1-Power per flow per pressure**. This value has units W/((m³/s)-Pa) and is used to scale the [Design electric power consumption](#) from the [Maximum flow rate](#) and the [Pressure rise](#). It is defined such that

Design electric power consumption = (Electric power per unit flow rate per unit pressure) * (Maximum flow rate) * Design pressure rise).

The default is 1.66667.

Fan total efficiency

This is the overall efficiency of the fan, i.e. the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. It is used when the [Design electric power consumption method](#) is set to **1-Autosize** and the [Design power sizing method](#) is set to **3-Total efficiency and pressure**. This value is used to determine the [Design electric power consumption](#) from the [Maximum flow rate](#) and the [Pressure rise](#). It is defined such that

Design electric power consumption = (Maximum flow rate) * (Design pressure rise) / (Fan Total Efficiency).

The default is 0.7.

Flow Rates

Maximum flow rate

Enter the full load air volumetric flow rate (m³/sec or ft³/min) installed in the HVAC system. This volume flow rate will be converted to a mass flow rate using an altitude-adjusted standard density of dry air at 20 °C drybulb. This full-speed flow rate and serves as the upper limit for fans that can vary their flow rate.

This field can be autosized and is greyed out if the parent HVAC component (e.g. AHU) defines the design air flow rate.

Motor

Motor efficiency

The fan shaft power divided by the electrical power consumed. Must be between 0 and 1.

Motor in airstream fraction

This is the fraction of the motor heat that is added to the air stream. The value must be between 0 and 1. A value of 0 means fan motor is located completely outside of the air stream and none of the motor's heat is added to the air stream. A value of 1.0 means the motor is located completely inside of air stream and all of the motor's heat is added to the air stream.

Note: Regardless of the value here there will be heat added to the air stream as a result of the work done to move the air. This setting only describes what happens to the heat generated as a result of the motor's inefficiency. The heat lost from the motor that is not added to the air stream can be added to the surrounding thermal zone where the motor is located using the settings below.

Motor loss added to zone

The heat lost from the motor that is not added to the air stream can be added to the thermal zone where the motor is located by checking this checkbox and selecting the zone in the setting below. If the fan is outdoors, or the motor's thermal losses are not to be modeled then leave this unchecked.

Motor loss zone

When the **Motor loss added to zone** checkbox is checked, you must select the zone in which the fan motor is located. In this case, the portion of the motor's thermal losses that are not added to the air stream are added to the surrounding thermal zone as internal heat gains.

Motor loss radiative fraction

When the **Motor loss added to zone** checkbox is checked, you can define the split between thermal radiation and convection for the heat losses from the fan motor. If this field is left at the default zero value all the losses will be convective. Values should be between 0 and 1.

Speed Control

Speed control method

This setting is used to select how the fan speed can be varied. There are two choices:

- **1-Continuous**, which indicates that the fan speed is variable and can change smoothly up to the **Maximum flow rate**.
- **2-Discrete**, which indicates that the fan can operate only at specific speed settings and cannot be continuously varied.

This input informs the program how power should be calculated with Discrete control using time-weighted averaging and Variable control using flow-weighted averaging.

Tip: For constant volume or on-off fans use **2-Discrete** with [Number of speeds](#) set to 1. For variable air volume fans use **1-Continuous**, in which case, a fan performance curve must be selected for [Electric power function of flow fraction curve](#).

Electric power minimum flow rate fraction

This setting is only available when the [Speed control method](#) is set to **1-Continuous**. It is used to describe how low a variable speed fan can be operated. This value is used to calculate the fan power at low flow rates but it does not enforce a lower end of the air flow during simulation. The value is a fraction of the [Maximum flow rate](#) and should be between 0 and 1.

Electric power function of flow fraction curve

Select the performance curve that describes how electric power consumption varies with air flow rate. The independent “x” variable of the performance curve is a normalized flow fraction defined as the current flow rate divided by the [Maximum flow rate](#). The model actually uses the ratio of (moist) air mass flow rates with the numerator taking account of humidity and barometric pressure. The dependent variable that is the result of the performance curve or lookup table is a fraction that is multiplied by the [Design electric power consumption](#) to determine the electric power use as a function of flow rate. Any of the single-independent-variable curves can be used.

This field is available if the [Speed control method](#) is set to **1-Continuous**. It is also used when the [Speed control method](#) is set to **2-Discrete** and the [Number of speeds](#) is greater than 1 and [Electric power fraction from curve](#) is checked.

Number of speeds

This numeric field is used to specify the number of different speed levels available when Speed Control Method is set to Discrete. This field and the remaining field sets are not used when the [Speed control method](#) is set to **1-Continuous**. For a constant volume fan enter a value of 1.0. A value of 1.0 will use the fan's maximum design and no additional field sets are needed. When set to a value greater than 1 then a pair of flow and power fraction inputs are provided for each speed in the remaining input fields.

Electric power fraction from curve

Check this checkbox is available when [Speed control method](#) is set to **2-Discrete** and the [Number of speeds](#) is greater than 1. In this case checking this checkbox indicates that EnergyPlus should calculate the electric power fraction for each discrete speed.

Paired values of Speed flow fraction and Speed electric power fraction

Enter a pair of values for the flow fraction and electric power fraction for each speed. The sets should be defined in increasing order so that the flow fractions become larger in subsequent field sets. Typically the highest speed level will match the design maximum and have fractions of 1.0.

Speed <#> Flow fraction

This is the flow fraction for the fan speed. It is multiplied by the [Maximum flow rate](#) to obtain the flow rate when operating at this speed.

Speed <#> Electric power fraction

This is the electric power fraction for the fan speed. It is multiplied by the [Design electric power consumption](#) to obtain the power consumption when operating at this speed. This field is available only if the [Electric power fraction from curve](#) checkbox is unchecked. Otherwise, if it is checked, the power at this speed will be determined using the performance curve selected for [Electric power function of flow fraction curve](#).

Operation

Availability schedule

This is the [Schedule](#) that defines whether the fan can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the fan is off.

This setting is non-editable in cases where the operation availability schedule is defined by the parent HVAC component (e.g. AHU).

Fan - Zone Exhaust

The zone exhaust fan provides a way to extract zone air to outside. It is a standalone component and unlike the other Detailed HVAC fans it does not link in with the main Air loop. It can also impact air flows in central air handlers by decreasing the flow of return air and sometimes increasing the outdoor air flow rate.

There are several control options available for the exhaust fan including an on/off availability schedule, interaction with system availability managers, minimum zone air temperature control limits and a variable flow fraction schedule. The way in which the exhaust fan impacts central air system can be controlled by declaring what portion of the flow has been “balanced” by simple airflow from infiltration, ventilation, or mixing. However it is important to note that presence of an exhaust fan does not by itself drive any simple airflow such as infiltration, ventilation, or zone mixing.

Note: When used with **Calculated natural ventilation**, Zone exhaust fans can take part in the Airflow Network causing a negative pressure in the zone which can be balanced by flows into the zone through other openings and cracks. In this case a single corresponding [vent](#) from the **Zone Exhaust Fans** category must be placed on an *external* surface of the building zone.

Note: To obtain balancing when using **Scheduled natural ventilation** the main natural ventilation airflow must be coordinated with the flows defined for the exhaust fan as there is no comprehensive automatic mass balancing between air system flows, exhaust flows, and the separate simple airflows.

Zone exhaust fans differ from the other fans in EnergyPlus HVAC in that they can stand on their own in a zone rather than serving as one part of an HVAC air system.

Summary of zone exhaust fan data entry

A zone exhaust fan is defined differently depending on whether the Calculated natural ventilation model option is selected or not.

- **When *not* using Calculated natural ventilation** simply add an Exhaust fan to the HVAC zone and make any settings on the dialog.
- **When using Calculated natural ventilation** then as well as the Exhaust fan in the HVAC zone you must also include a single external *rectangular* vent from the **Zone Exhaust Fans** category somewhere in the zone by drawing it at surface level on an *exterior* surface. The purpose of the vent is to include the zone exhaust fan as an airflow path in the EnergyPlus Airflow Network. The numbered steps that follow refer to the screenshot below. Having drawn the vent object at surface level:
 1. Navigate to the vent object.
 2. Select the **vent type** model data on the Openings tab.
 3. Select the pre-defined **Zone Exhaust Fan** vent component.
 4. Alternatively create a new vent component and set its category to **Zone Exhaust Fans**.

The end result should be that each zone with an HVAC Exhaust fan has exactly 1 *rectangular* vent from the **Zone Exhaust Fans** category placed on an *exterior* surface.

Tip: It is possible to simply add a single zone exhaust fan to a zone group without any other HVAC equipment to simulate cases where no HVAC equipment (apart from the exhaust fan) is required. Zone exhaust fans can equally be mixed with other zone equipment data including standard extract components.

Name

A unique user-assigned name for an instance of a zone exhaust fan. Any reference to this fan by another object will use this name.

End-Use subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Kitchen Exhaust", "Fume Hoods", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter object). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the fan will be assigned to the "General" end-use subcategory.

Fan Data

Fan total efficiency

This is the overall efficiency of the fan, i.e. the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is the power delivered to the air divided by the shaft power. The power delivered to the air is the mass flow rate of the air

multiplied by the pressure rise divided by the air density. This efficiency must be between 0 and 1. The default is 0.6.

Pressure rise

The pressure rise (in Pascals or inH2O) at full flow and standard (sea level) conditions (20°C and 101325 Pa).

Maximum flow rate

The full load air volumetric flow rate (in m3/sec or ft3/min) at standard temperature and pressure (dry air at 20°C drybulb). The program does use local barometric pressure to account for altitude using equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p = 101325 * (1 - 2.25577E-05 * Z)^{5.2559}$$

where p=pressure in Pa and Z=altitude in m

System availability manager coupling mode

This setting can be used to control whether the exhaust fan should operate independently or not. For example, when a night cycle availability manager turns on the central air system for freeze protection, this field can be used to control if the zone exhaust fans should also run at the same time or not. The options are:

- **1-Coupled** which indicates that the exhaust fan should be integrated with the system availability manager so that the fan runs when the air system is forced to run.
- **2-Decoupled** which indicates that the exhaust fan should operate on its own and ignore the system availability manager's requests so that the exhaust fan can remain off when the air system runs.

The default is **1-Coupled**.

Apply minimum zone temperature limit schedule

If you would like to define a minimum zone temperature limit schedule (below) then check this option.

Minimum zone temperature limit schedule

This field is optional. If it is not used then there will be no temperature-related control over the operation of the exhaust fan. If the option is used, then enter the name of a schedule with values for zone temperature values (in °C). The fan's control will be based on a comparison between the current zone air temperature and the schedule values. If the zone is warmer than the scheduled limit, then the fan will operate. When balancing with Scheduled natural ventilation, this feature can be used to coordinate exhaust fan operation with the main natural ventilation controls for minimum indoor temperature.

Apply balanced exhaust fraction schedule

If you would like to define a balanced exhaust fraction schedule (below) then check this option.

Balanced exhaust fraction schedule

This field is optional. If it is not used, then all the exhaust air flow is assumed to be unbalanced by any simple airflows, such as infiltration, ventilation, or zone mixing. Unbalanced exhaust is then modelled as being provided by the outdoor air system in the central air system. The modelling of unbalanced will reduce the flow rates at the zone's return air node by the flow rate that is being exhausted and will insure that the outdoor air flow rate is sufficient to serve the exhaust. If this field is used, then enter the name of a schedule with fractional values between 0.0 and 1.0, inclusive. This fraction is applied to the exhaust fan flow rate and the model tracks the portion of the exhaust that is "balanced." Balanced exhaust is then modelled as being provided by simple airflows and does not impact the central air system return air or outdoor air flow rates. For example, if a kitchen zone with an exhaust fan is designed to draw half of its make up air from a neighbouring dining room and the other half from the outdoor air system, then a schedule value of 0.5 could be used here.

Operation

Availability schedule

The availability schedule denotes whether the fan can run during a given time period. A schedule value of 0 indicates that the fan is off for that time period. A schedule value greater than 0 indicates that the fan can operate during the time period.

Apply flow fraction schedule

If you would like to define a Flow fraction schedule (below) then check this option.

Flow fraction schedule

This field is optional. If it is not used then the fan operates at the maximum flow rate. If a schedule is selected here, then it should contain fractional values between 0.0 and 1.0, inclusive. During the simulation the flow rate provided by the fan will be this fraction times the maximum flow rate. This allows a variable speed exhaust fan to be modelled according to a schedule.

Humidifier - Steam Electric

Humidifier:Steam:Electric

Used in:

- Air Handling Units

The electric steam humidifier is a component that represents an electrically heated, self contained steam humidifier. The component uses electrical energy to convert ordinary tap water to steam which it then injects into the supply air stream by means of a blower fan. The actual unit might be an electrode-type humidifier or a resistance-type humidifier.

The humidifier model includes local control of the humidifier unit to meet a humidity ratio setpoint on its air outlet node.

Note: To ensure that the humidifier will add moisture to meet the humidity ratio setpoint, a Minimum humidity [Setpoint manager](#) must be added *immediately downstream* of the Humidifier (**4-Multi-zone minimum humidity average** or **6-Multi-zone humidity minimum** or **8-Single zone humidity minimum**).

More information on controlling humidity is available in the [Humidity control](#) section.

General

Name

A unique system assigned name for a particular humidifier unit. Any reference to this unit by another object will use this name.

Rated capacity

The nominal full output water addition rate of the unit (in m³/sec or gal/min of water at 5.05°C).

Note: The Rated capacity *cannot* be autosized in current versions of EnergyPlus, but if you are not sure of the correct value to use, it is possible to enter a very high value (e.g. 1m³/s) to ensure that humidification loads can always be met.

Rated power

The nominal full output power consumption of the unit (in W), exclusive of the blower fan power consumption and any standby power. This field can be autosized. When it is autosized, the calculations are based on the [rated capacity](#) and the enthalpy rise of the feed water from the reference temperature of liquid water at 20°C to a saturated steam at 100°C.

Rated fan power

The nominal full output power consumption of the blower fan (in W).

Standby power

The standby power consumption (in W). This amount of power will be consumed whenever the unit is available (as defined by the availability schedule).

Operation

Availability schedule

[Schedule](#) that defines whether the unit can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the fan can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Humidifier - Steam Electric Outputs

HVAC,Average,Humidifier Water Consumption Rate[m3/s]
 HVAC,Sum,Humidifier Water Consumption[m3]
 HVAC,Average,Humidifier Electric Power[W]
 HVAC,Sum,Humidifier Electric Consumption[J]
 Zone,Meter,Humidifier:Water [m3]
 Zone,Meter,Humidifier:Electricity [J]
 HVAC,Average,Humidifier Water From Storage Tank Rate [m3/s]

 HVAC,Sum,Humidifier Water Starved By Storage Tank [m3]
 Zone,Meter,Humidifier:MainsWater [m3]
 HVAC,Sum,Humidifier Water Mains Draw [m3]

Humidifier Water Consumption Rate[m3/s]

This field reports the water consumption rate of the steam humidifier in cubic meters of water per second.

Humidifier Water Consumption[m3]

This output is the cubic meters of water consumed by the steam humidifier over the timestep being reported.

Humidifier Electric Power[W]

This output is the electricity consumption rate in Watts of the steam humidifier.

Humidifier Electric Consumption[J]

This is the electricity consumption in Joules of the steam humidifier over the timestep being reported.

Humidifier:Water [m3]

This meter output contains the sum of the water consumed (in cubic meters of water during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

Humidifier:Electricity [J]

This meter output contains the sum of the electricity consumed (in Joules during the report timestep) by all the steam humidifiers at the HVAC level in the simulation.

Humidifier Water From Storage Tank Rate [m3/s]

Humidifier Water From Storage Tank [m3]

These outputs contain the rate and volume of water obtained from water storage tank. These are only present if the humidifier is connected to a Water Storage Tank for its water supply.

Humidifier Water Starved By Storage Tank Rate [m3/s]

Humidifier Water Starved By Storage Tank [m3]

These outputs contain the rate and volume of water that could not be obtained from the water storage tank. The component will still operate as if it did get all the water with the balance obtained directly from the mains

Humidifier Water Mains Draw [m3]

This output contains the volume of water obtained from the mains.

Evaporative Cooler Data

An evaporative cooler is a type of cooling component that provides free adiabatic cooling to an air stream purely through the evaporation of water. Evaporative cooling differs from typical air conditioning systems which use vapour-compression or absorption refrigeration cycles. Evaporative cooling works by employing water's large enthalpy of vaporisation. The temperature of dry air can be dropped significantly through the phase transition of liquid water to water vapour, which requires much less energy than refrigeration. In dry climates, it also has the added benefit of conditioning the air with more moisture for the comfort of occupants. Unlike refrigeration, it requires a water source, and must continually consume water to operate.

As water is evaporated, energy is lost from the air, reducing its temperature. The lowest temperature that an evaporative cooler can cool to is the incoming air wet-bulb temperature.

Two types of evaporative cooler are supported by DesignBuilder EnergyPlus: direct and indirect systems.

- **Direct** evaporative cooling (open circuit) is used to lower the temperature of air by using latent heat of evaporation, changing liquid water to water vapour. In this process, the energy in the air does not change. Warm dry air is changed to cool moist air. The heat of the outside air is used to evaporate water.
- **Indirect** evaporative cooling (closed circuit) is similar to direct evaporative cooling, but uses some type of heat exchanger. The cooled moist air never comes in direct contact with the conditioned environment.

In DesignBuilder evaporative coolers can be placed within an AHU in much the same way that water and DX cooling coils are placed. They can also be selected as outdoor air [pretreatment](#) components within the AHU dialogs. Five types of evaporative coolers are provided any of which can be selected when placing the component or from the Evaporative cooler dialog:

- [1-Direct CelDekPad](#)
- [2-Direct Research Special](#)
- [3-Indirect CelDekPad](#)
- [4-Indirect Wet Coil](#)
- [5-Indirect Research Special](#)

Evaporative Cooler - Direct CelDekPad

EvaporativeCooler:Direct:CelDekPad

Used in:

- Air Handling Units

The direct stage, shown in the figure below, consists of a rigid media evaporative pad, with water recirculated from a reservoir. The water is pumped from the reservoir to a water distribution header, for water feed by gravity from above the media. The evaporative pad provides the area for the adiabatic saturation of the air. While the process provides a lower dry-bulb temperature, the moisture content of the leaving air is higher than the entering condition. The direct stage is used for comfort cooling in a building where adding humidity to the air can be tolerated.

Direct Stage Evaporative Cooler

The thermodynamic process is a simultaneous heat and mass transfer, or adiabatic cooling, and follows a constant enthalpy line on the psychrometric chart, it is shown in the figure below as a process from A to B. Since the deviation of the constant wet-bulb line and the constant enthalpy line is small, it is assumed that the wet-bulb temperature is constant across the direct evaporative stage.

Psychrometric Chart - Constant Enthalpy

If the direct evaporative process were 100% efficient, the leaving dry-bulb temperature would equal the entering wet-bulb temperature. The efficiency of the direct evaporative process is less than 100% and by defining saturation efficiency (ϵ_{se}) for the direct stage or evaporative pad, the leaving dry-bulb temperature can be expressed by the following equation.

$$T_{db\ supout} = T_{db\ supin} - \epsilon_{se} \cdot (T_{db\ supin} - T_{wb\ supin})$$

General

Name

A unique name for an instance of an evaporative cooler which is predetermined by DesignBuilder.

Type

Select the type of evaporative cooler from the list of options:

- [1-Direct CelDekPad](#), the cooler described here, a direct evaporative cooler with rigid media evaporative pad and water recirculated from a reservoir.
- [2-Direct Research Special](#), similar to [1-Direct CelDekPad](#) but with methods to specify variable effectiveness based on primary air flow rate and a way to control the cooler operating range based on temperature limits.
- [3-Indirect CelDekPad](#), an indirect evaporative cooler with a rigid media pad, similar to the direct evaporative cooler.
- [4-Indirect Wet Coil](#), an indirect evaporative cooler where water is sprayed directly on the tubes of the heat exchanger.
- [5-Indirect Research Special](#), similar to the other indirect evaporative coolers, but it provides additional flexibility including a way to specify the source of secondary air.

Settings

Direct pad area

The face area of the evaporative pad (in m² or ft²). With the area and mass flow rate, the air velocity is calculated and is used to determine the saturation efficiency.

Direct pad depth

The depth of the evaporative pad (in m or in). The pad depth is used to determine the saturation efficiency.

Recirculating water pump power consumption

This field is used to specify the power consumed by the evaporative cooler recirculating pump (in W).

Operation

Availability schedule

[Schedule](#) that defines when the coil is available, i.e. whether the evaporative cooler can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Evaporative Cooler - Direct Research Special

EvaporativeCooler:Direct:ResearchSpecial

Used in:

- Air Handling Units

This cooler is similar in principal to the [Direct CelDekPad](#). The model differs in that it gives the user a simple way of specify the cooler effectiveness. Using the Research Special input object also allows the cooler to control the amount of cooling based on node setpoints, controlled by [Setpoint managers](#). This avoids problems from over cooling when conditions are such that loads are low and cooling power is high. Water pump power is assumed to vary linearly when the cooler is operating at less than full capacity.

The model allows the effectiveness to be vary depending on the primary air flow rates. The design effectiveness can be modified by multiplying by an Effectiveness flow fraction modifier curve. The flow fraction is the ratio of the current primary airflow rate to the design flow rate. The recirculating and spray water pump power is assumed to vary with the primary air flow. The design pump power is modified using user specified pump modifier curve value. The normalized pump power modifier curve is a function of primary air flow fraction as a independent variable.

Also the direct evaporative cooler operating range can be controlled depending on the entering air dry bulb and wet bulb temperatures. The operating range can be controlled based on minimum and maximum inlet node air temperature limits. The evaporative cooler can be turned on or off depending user specified minimum and maximum temperature limits. If the inlet node entering air temperature is lower or higher than the minimum and maximum limits, respectively, then the evaporative cooler is turned off. The operating range control feature is primarily intended for application in data centres.

General

Name

A unique name for an instance of an evaporative cooler which is predetermined by DesignBuilder.

Type

Select the type of evaporative cooler from the list of options:

- [1-Direct CelDekPad](#), a direct evaporative cooler with rigid media evaporative pad and water recirculated from a reservoir.
- [2-Direct Research Special](#), the cooler described here which is similar to [1-Direct CelDekPad](#) but with methods to specify variable effectiveness based on primary air flow rate and a way to control the cooler operating range based on temperature limits.
- [3-Indirect CelDekPad](#), an indirect evaporative cooler with a rigid media pad, similar to the direct evaporative cooler.
- [4-Indirect Wet Coil](#), an indirect evaporative cooler where water is sprayed directly on the tubes of the heat exchanger.
- [5-Indirect Research Special](#), similar to the other indirect evaporative coolers, but it provides additional flexibility including a way to specify the source of secondary air.

Settings

Primary design air flow rate

This autosizable setting is the primary air design air flow rate (in m³/s or ft³/min). If the evaporative cooler is on main air loop branch, the design flow rate is the same as branch design flow rate, or else if it is on outdoor air system it will be the maximum of the outdoor air design flow rate and the half of the primary air flow rate on the main air loop branch.

Cooler design effectiveness

This setting specifies the effectiveness of the cooler at design flow rate that is applied to the wet-bulb depression to determine the conditions leaving the cooler. This model assumes that the effectiveness can vary with supply air flow rate. For effectiveness variation with supply air flow fraction enter the [Effectiveness flow ratio modifier curve](#) below. The flow fraction is the ratio of the sum of current primary air and secondary air sides flow rates and the sum of the design flow rates.

Effectiveness flow ratio modifier

If an Effectiveness flow ratio modifier curve (below) is to be specified then check this checkbox. If this option is not checked then the effectiveness is assumed to be constant.

Effectiveness flow ratio modifier curve

This curve modifies the [Cooler effectiveness](#) design value (above) by multiplying the value by the result of this curve. The modifying curve is a function of flow fraction, which is the ratio of the current primary air flow rates divided by the design primary air flow rates. Any curve with one independent variable can be used. Select a curve from one of these categories:

- [Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

Drift loss fraction

This field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media by winds and escape the air system. The value entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

Recirculating Water

Recirculating water pump design power

This is the nominal water recirculating and spray pump power of evaporative cooler at primary air design flow rates and cooler design effectiveness. This setting is autosizable.

Water pump power sizing factor

This numeric input field value is recirculating water pump sizing factor (in W/(m³/s) or W/gpm). This field is used when the previous field is set to autosize. The pump design electric power is scaled with Secondary Design Air Flow Rate. The default value is 90.0 W/(m³/s), i.e. Pump power / Primary air design flow rate = 90 W/(m³/s). Typical values range from 55.0 to 150.0 W/(m³/s).

Water pump power modifier

Select this option to apply a [Water pump power modifier curve](#). If this option is not checked then the pump power is assumed to vary linearly with the load.

Water pump power modifier curve

Select a dimensionless normalized pump power modifying curve. This curve modifies the pump electric power by multiplying the design power by the result of this curve. The normalized curve is a function of the primary air flow fraction as independent variable. The curve generates a value of 1.0 at a flow fraction of 1.0. The flow fraction is the ratio of the primary air during current operation divided by [Primary design air flow rate](#). Any curve with one independent variable can be used. Select a curve from one of these categories:

- [Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

Temperature Limits

Evaporative operation minimum dry-bulb temperature

To define a dry-bulb temperature lower limit for evaporative cooler operation check this checkbox. Otherwise, if this option is unchecked then there is no dry-bulb temperature lower limit for evaporative cooler operation.

Minimum limit dry-bulb temperature

This setting defines the evaporative cooler inlet node dry-bulb temperature minimum limit (in °C or °F). The evaporative cooler will be turned off when evaporator cooler air inlet node dry-bulb temperature falls below this value. The typical minimum value is 16°C.

Evaporative operation maximum limit wet-bulb temperature

To define a wet-bulb temperature upper limit for evaporative cooler operation check this checkbox. Otherwise, if this option is unchecked then there is no wet-bulb temperature upper limit for evaporative cooler operation.

Minimum limit dry-bulb temperature

This setting defines the evaporative cooler air inlet node air wet-bulb temperature maximum limit (in °C or °F). When the evaporative cooler air inlet node air wet-bulb temperature exceeds this limit, then the evaporative cooler is turns off. The typical maximum value is 24°C.

Evaporative operation maximum limit dry-bulb temperature

To define a dry-bulb temperature upper limit for evaporative cooler operation check this checkbox. Otherwise, if this option is unchecked then there is no dry-bulb temperature upper limit for evaporative cooler operation.

Maximum limit dry-bulb temperature

This setting defines the evaporative cooler air inlet node dry-bulb temperature maximum limit (in °C or °F). The evaporative cooler will be turned off when the evaporative cooler air inlet node dry-bulb temperature exceeds this value. The typical maximum value is 28°C.

Blowdown

Blowdown On

Select this option to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation.

Blowdown concentration ratio

The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

Operation

Availability schedule

[Schedule](#) that defines when the coil is available, i.e. whether the evaporative cooler can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Evaporative Cooler - Indirect CelDekPad

EvaporativeCooler:Indirect:CelDekPad

Used in:

- Air Handling Units

The dry coil indirect evaporative cooler has a rigid media pad, similar to the direct evaporative stage, where the adiabatic cooling takes place. The secondary air enters the evaporative cooler at ambient conditions, is passed into the rigid media pad and enters an air to air heat exchanger where it cools the supply air flowing through the heat exchanger tubes (see diagram below). The moist secondary air is then exhausted to the environment. The secondary air stream has its own fan and consists of a rigid media evaporative pad with water recirculated from a reservoir. The water is pumped from the reservoir to a water distribution header for water feed by gravity from above the media. The evaporative pad provides the area for the adiabatic saturation of the air.

The process that the secondary air goes through, A to C to D, is shown by the dashed lines in the following figure. Process A to C is adiabatic cooling in the rigid media pad. Then the air enters the shell side of the heat exchanger and is sensibly heated from C to D by the warm supply air passing through the tube side. The secondary air inlet is modeled as a separate stream of outdoor air and the user has the option of defining the name of an outdoor air node.

The advantage of the dry coil heat exchanger is that the heat exchanger does not have the evaporation taking place on the outside of the tubes, thus no mineral deposits are left on the heat exchange surface to reduce the efficiency of the heat exchanger. The rigid media pads are designed to flush the mineral deposits to the sump, so the saturation efficiency of the pad stays relatively constant.

General

Name

A unique name for an instance of an evaporative cooler which is predetermined by DesignBuilder.

Type

Select the type of evaporative cooler from the list of options:

- [1-Direct CelDekPad](#), a direct evaporative cooler with rigid media evaporative pad and water recirculated from a reservoir.
- [2-Direct Research Special](#), similar to [1-Direct CelDekPad](#) but with methods to specify variable effectiveness based on primary air flow rate and a way to control the cooler operating range based on temperature limits.
- [3-Indirect CelDekPad](#), the indirect evaporative cooler described here with a rigid media pad, similar to the direct evaporative cooler.
- [4-Indirect Wet Coil](#), an indirect evaporative cooler where water is sprayed directly on the tubes of the heat exchanger.
- [5-Indirect Research Special](#), similar to the other indirect evaporative coolers, but it provides additional flexibility including a way to specify the source of secondary air.

Settings

Direct pad area

The face area of the evaporative pad (in m² or ft²). With the area and mass flow rate, the air velocity is calculated and is used to determine the saturation efficiency on the secondary side of the evaporative cooler.

Direct pad depth

The depth of the evaporative pad in meters. The pad depth is used to determine the saturation efficiency on the secondary side of the evaporative cooler.

Indirect heat exchanger effectiveness

This field is used to specify the effectiveness of the indirect heat exchanger between the primary and secondary air flow.

Recirculating water pump power consumption

This field is used to specify the power consumed by the evaporative cooler recirculating pump (in W).

Secondary Fan

The secondary flow is sourced from outside air and blown over the

Secondary fan flow rate

This field is used to specify the secondary fan flow rate and is specified in m³/s or ft³/min.

Secondary fan efficiency

This field is used to specify the total efficiency of the fan and is used to calculate the power consumed by the evaporative cooler secondary fan. Input values should be between 0 and 1.

Secondary fan delta pressure

This field is used to specify the delta pressure across the secondary stage of the evaporative cooler (in Pa or in H₂O).

Operation

Availability schedule

[Schedule](#) that defines when the coil is available, i.e. whether the evaporative cooler can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Evaporative Cooler - Indirect Wet Coil

EvaporativeCooler:Indirect:WetCoil

Used in:

- Air Handling Units

The wetted coil evaporative cooler shown in the figure below, has water sprayed directly on the tubes of the heat exchanger where latent cooling takes place. The vaporization of the water on the outside of the heat exchanger tubes allows the simultaneous heat and mass transfer which removes heat from the supply air on the tube side. Secondary air at ambient conditions is passed over the wet coil and is exhausted to outside. The secondary air stream has its own fan.

Evaporative Cooler – Indirect Wet Coil

The process that the secondary air goes through, A to C on the following figure, is a path of simultaneous heat and mass transfer, but it does not follow a line of constant enthalpy as in the direct stage. The process is not adiabatic due to the heat gain from the supply air flowing through the tubes of the heat exchanger.

Secondary Air Process – Indirect Wet Coil Evaporative Cooler

General

Name

A unique name for an instance of an evaporative cooler which is predetermined by DesignBuilder.

Type

Select the type of evaporative cooler from the list of options:

- [1-Direct CelDekPad](#), a direct evaporative cooler with rigid media evaporative pad and water recirculated from a reservoir.
- [2-Direct Research Special](#), similar to [1-Direct CelDekPad](#) but with methods to specify variable effectiveness based on primary air flow rate and a way to control the cooler operating range based on temperature limits.
- [3-Indirect CelDekPad](#), an indirect evaporative cooler with a rigid media pad, similar to the direct evaporative cooler.
- [4-Indirect Wet Coil](#), the indirect evaporative cooler described here where water is sprayed directly on the tubes of the heat exchanger.
- [5-Indirect Research Special](#), similar to the other indirect evaporative coolers, but it provides additional flexibility including a way to specify the source of secondary air.

Settings

Coil maximum efficiency

The maximum efficiency of the stage is a combination of the efficiency due to the simultaneous heat and mass transfer on the outside of the tube and the efficiency of the heat exchanger. This value can be higher than the dry coil overall efficiency since the convective coefficients on the outside of the tube are larger.

Coil flow ratio

The Coil flow ratio is determined from performance data. The Coil Flow Ratio tells how quickly the efficiency of the stage would decrease with a mismatch of the supply and secondary flows.

Recirculating water pump power consumption

This field is used to specify the power consumed by the water pump that circulates water (in W).

Secondary Fan

Secondary fan flow rate

This field is used to specify the secondary fan flow rate and is specified in m3/s or ft3/min.

Secondary fan total efficiency

This field is used to specify the total efficiency of the fan and is used to calculate the power consumed by the evaporative cooler secondary fan. Input values should be between 0 and 1.

Secondary fan delta pressure

This field is used to specify the delta pressure across the secondary stage of the evaporative cooler (in Pa or in H2O).

Blowdown

Blowdown On

Select this option to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation.

Blowdown concentration ratio

The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

Operation

Availability schedule

[Schedule](#) that defines when the coil is available, i.e. whether the evaporative cooler can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Evaporative Cooler - Indirect Research Special

EvaporativeCooler:Indirect:ResearchSpecial

Used in:

- Air Handling Units

The EnergyPlus Indirect Research Special is similar in principal to the [Indirect CelDekPad](#) and [Indirect WetCoil](#) evaporative coolers, but it provides some additional flexibility. The model differs in that it gives the user more flexibility to specify the source of secondary air. The cooler effectiveness with respect to wet-bulb depression is allowed to go beyond 1.0. Using the Research Special input object also allows the cooler to control the amount of cooling based on node setpoints (controlled by Setpoint Managers). This avoids

problems from over cooling when conditions are such that loads are low and cooling power is high. Fan power is assumed to vary linearly when the cooler is operating at less than full capacity.

The indirect evaporative cooler research special calculation procedure allows accounting for dry and wet effectiveness value variation with flow fraction. Two effectiveness modifier curves are included as optional user inputs for this purpose. Effectiveness modifier curves operate on the design dry and wet effectiveness values. The flow fraction is calculated as a ratio of the sum of current primary and secondary air flow rates to the sum of the design flow rates. Model also accounts for fan and recirculation water pump power variation with secondary air flow rates using pump power modifying curve. The fan power is calculated by multiplying the design fan power using fan power modify curve value evaluated at current secondary air flow fraction. Similarly, recirculating pump power is calculated by multiplying the design pump power by pump power modifier curve value evaluated at current secondary air flow fraction. If the secondary air fan and recirculating pump power modifier curves are not specified, then fan and pump power are assumed to vary linearly with part load fraction.

The cooler effectiveness with respect to wet-bulb depression is allowed to go beyond 1. Fan power is assumed to vary linearly when the cooler is operating at less than full capacity.

General

Name

A unique name for an instance of an evaporative cooler which is predetermined by DesignBuilder.

Type

Select the type of evaporative cooler from the list of options:

- [1-Direct CelDekPad](#), a direct evaporative cooler with rigid media evaporative pad and water recirculated from a reservoir.
- [2-Direct Research Special](#), similar to [1-Direct CelDekPad](#) but with methods to specify variable effectiveness based on primary air flow rate and a way to control the cooler operating range based on temperature limits.
- [3-Indirect CelDekPad](#), an indirect evaporative cooler with a rigid media pad, similar to the direct evaporative cooler.
- [4-Indirect Wet Coil](#), an indirect evaporative cooler where water is sprayed directly on the tubes of the heat exchanger.
- [5-Indirect Research Special](#), the model described here, similar to the other indirect evaporative coolers, but it provides additional flexibility including a way to specify the source of secondary air.

Settings

Primary design air flow rate

This autosizable setting is the primary air design air flow rate (in m³/s or ft³/min). If the evaporative cooler is on main air loop branch, the design flow rate is the same as branch design flow rate, or else if it is on outdoor air system it will be the maximum of the outdoor air design flow rate and the half of the primary air flow rate on the main air loop branch.

Cooler wet-bulb design effectiveness

This setting specifies the design effectiveness that is applied to the wet-bulb depression to determine the conditions leaving the cooler. This effectiveness is a complicated function of the efficiency with which heat and mass are transferred on the secondary side and the efficiency of heat exchange between the secondary and primary flows. The model assumes that the effectiveness a function of flow fraction. The flow fraction is the ratio of the sum of primary air and secondary air current flow rates and the sum of the primary air and secondary air design flow rates.

Wet-bulb effectiveness flow ratio modifier

Check this option to allow the Cooler wet-bulb design effectiveness specified above to be modified by a curve based on flow fraction. If this option is not checked then the wet-bulb effectiveness is assumed to be the constant value entered above.

Wet-bulb effectiveness flow ratio modifier curve

This curve modifies the wet-bulb effectiveness design value specified above by multiplying it by the result of this curve. The modifying curve is a function of flow fraction, which is the ratio of the sum of the primary and secondary flow rates divided by the sum of the design flow rates. Any curve with one independent variable can be used. Select a curve from one of these categories:

- [Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

Cooler dry-bulb design effectiveness

Enter the dry-bulb design effectiveness of the evaporative cooler. This is the nominal design dry bulb effectiveness with respect to dry bulb temperature difference, i.e., dry operation and at design air flow rates, and no water evaporation or spraying on the secondary side.

Dry-bulb effectiveness flow ratio modifier

Check this option to allow the Cooler dry-bulb design effectiveness specified above to be modified by a curve based on flow fraction. If this option is not checked then the dry-bulb effectiveness is assumed to be the constant value entered above.

Dry-bulb effectiveness flow ratio modifier curve

The dry-bulb effectiveness entered in the previous field can be modified by multiplying by the result of this curve. The curve is evaluated using flow fraction as the independent variable. The flow fraction is the ratio of sum of the primary and secondary flow rates divided by the sum of the design flow rates. Any curve with one independent variable can be used. Select a curve from one of these categories:

- [Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

Dew-point effectiveness factor

This field specifies an effectiveness that is applied to the dew-point depression to determine a bound for the conditions leaving the cooler. The model uses the warmer of the two temperatures determined from wet-bulb depression and dew-point depression.

Drift loss fraction

This field is optional and can be used to model additional water consumed by the cooler from drift. Drift is water that leaves the cooling media as droplets and does not evaporate into the process air stream. For example, water may get blown off the evaporative media by winds and escape the air system. The value entered here is a simple fraction of the water consumed by the cooler for normal process evaporation. The amount of drift is this fraction times the water evaporated for the normal cooling process. This field can be left blank and then there will be no added water consumption from drift.

Recirculating Water

Recirculating water pump design power

This autosizable setting is the recirculating pump electric power at Secondary design air flow rate (in W). It is the nominal design pump power water recirculation and spray for evaporation at design secondary air flow rates and cooler design effectiveness.

Water pump power sizing factor

This numeric input field value is recirculating water pump sizing factor (in W/(m³/s) or W/gpm). This field is used when the previous field is set to autosize. The pump design electric power is scaled with Secondary Design Air Flow Rate. The default value is 90.0 W/(m³/s), i.e. Pump power / Primary air design flow rate = 90 W/(m³/s). Typical values range from 55.0 to 150.0 W/(m³/s).

Water pump power modifier

Select this option to apply a [Water pump power modifier curve](#). If this option is not checked then the pump power is assumed to be constant.

Water pump power modifier curve

Select a dimensionless normalized pump power modifying curve. The pump electric power is modified by multiplying the design power by the result of this curve. The normalized curve is a function of the secondary side flow fraction as independent variable. The curve generates a value of 1.0 at a flow fraction of 1.0. The flow fraction is the ratio of the primary air during current operation divided by [Primary design air flow rate](#). Any curve with one independent variable can be used. Select a curve from one of these categories:

- [Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

Secondary Air

Secondary air design flow rate

This field is used to specify the secondary air fan flow rate and is specified (in m³/s or ft³/min). This flow rate would typically be similar in magnitude to the flow through the primary side. The flow rate is used to determine parasitic fan energy and cooler effectiveness. The flow rate (and fan power) is effectively reduced by cycling when the amount of cooling needs to be restricted for control purpose. This field can be autosized. When this input is autosized, the program calculates it by scaling the [Primary design air flow rate](#) using secondary air scaling factor specified in the input field below.

Secondary air flow scaling factor

This setting is used to scale the secondary air design flow rate and is dimensionless. It is used when the previous field is set to autosize. The [Primary design air flow rate](#) is scaled using this factor to calculate the secondary design air flow rate.

Secondary air fan design power

This autosizable setting is the fan electric power at [Secondary design air flow rate](#). It is the nominal design electric power at full speed of the secondary air fan.

Secondary air fan sizing specific power

This input field value is secondary air fan sizing specific power (in W/(m³/s) or W/gpm). It is used when the previous field is set to autosize. The fan power is scaled with [Secondary design air flow rate](#).

Secondary air fan power modifier

The [Secondary air fan design power](#) above can be modified by a curve using the secondary side flow fraction as the independent variable. Check this option to modify the secondary fan power in this way. If this option is unchecked then the fan power is assumed to be constant.

Secondary air fan power modifier curve

The [Secondary air fan design power](#) above can be modified by multiplying by the result of this dimensionless normalized curve. The curve is a function of the secondary side flow fraction as the independent variable. The curve generates a value of 1.0 at a flow fraction of 1.0. The flow fraction is the secondary air flow rate during operation divided by [Secondary design air flow rate](#). Any curve with one independent variable can be used. Select a curve from one of these categories:

- [Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

Temperature Limits

Evaporative operation minimum dry-bulb temperature

To define a dry-bulb temperature lower limit for evaporative cooler operation check this checkbox. Otherwise, if this option is unchecked then there is no dry-bulb temperature lower limit for evaporative cooler operation.

Minimum limit dry-bulb temperature

This setting defines the evaporative cooler inlet node dry-bulb temperature minimum limit (in °C or °F). The evaporative cooler will be turned off when evaporator cooler air inlet node dry-bulb temperature falls below this value. The typical minimum value is 16°C.

Evaporative operation maximum limit wet-bulb temperature

To define a wet-bulb temperature upper limit for evaporative cooler operation check this checkbox. Otherwise, if this option is unchecked then there is no wet-bulb temperature upper limit for evaporative cooler operation.

Minimum limit dry-bulb temperature

This setting defines the evaporative cooler air inlet node air wet-bulb temperature maximum limit (in °C or °F). When the evaporative cooler air inlet node air wet-bulb temperature exceeds this limit, then the evaporative cooler is turns off. The typical maximum value is 24°C.

Evaporative operation maximum limit dry-bulb temperature

To define a dry-bulb temperature upper limit for evaporative cooler operation check this checkbox. Otherwise, if this option is unchecked then there is no dry-bulb temperature upper limit for evaporative cooler operation.

Maximum limit dry-bulb temperature

This setting defines the evaporative cooler air inlet node dry-bulb temperature maximum limit (in °C or °F). The evaporative cooler will be turned off when the evaporative cooler air inlet node dry-bulb temperature exceeds this value. The typical maximum value is 28°C.

Blowdown

Blowdown On

Select this option to model additional water consumed by the cooler from blowdown. Blowdown is water that is intentionally drained from the cooler's sump to offset the build up of solids in the water that would otherwise occur because of evaporation.

Blowdown concentration ratio

The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values are 3 to 5. The default is 3.0.

Operation

Availability schedule

[Schedule](#) that defines when the coil is available, i.e. whether the evaporative cooler can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Plant Loop Heat Pumps

A single physical water-to-water heat pump could potentially provide either heating only, cooling only or both heating and cooling. These 3 heat pump configuration types can be represented in DesignBuilder using **Heat pump - heating** and/or **Heat pump - cooling** components connected to hot and chilled water plant loops respectively. Where both heating and cooling are provided by the same physical heat pump both heating and cooling heat pumps must be included in the HVAC layout and the data entry for the heat pumps (especially flow rates), must be coordinated.

The Supply side of the heat pump may be connected to one of the following components:

- [Ground Heat Exchanger](#)
- [Cooling tower](#)
- [Fluid cooler](#)
- [Heat exchanger](#)

The schematic diagram below shows the layout and piping diagram of the water-to-water heat pump.

GSHP Loops

Ground source heat pumps systems are essentially made up of two loops (heating or cooling only cases) or three loops (combined heating and cooling):

- [HW loop](#) (for heating applications) - Hot water loop (Water-to-water heat pump heating)
- [CHW loop](#) (for cooling applications) - Chilled water loop (Water-to-water heat pump cooling)
- [Condenser loop](#) - typically a [Ground heat exchanger loop](#) (exchanges heat with ground via either surface, pond or vertical borehole types)

In addition to the above mandatory loops, the system may also require extra loops such as air loops for specific room/block applications.

Tip: You are advised to work through the [GSHP Example](#) before attempting to model these systems for the first time.

The screenshot below shows a typical GSHP layout diagram.

You can learn more about practical aspects of GSHP design and simulation for project work by watching our webinar: [Design and Modelling of Ground Source Heat Pump Systems](#)

Component descriptions:

- [Water to Water Heat Pump - Heating](#)
- [Water to Water Heat Pump - Cooling](#)

Configuring GSHPs In DesignBuilder

Because GSHPs cannot be autosized in EnergyPlus some care is required in setting up these systems. This section describes a process which ensures correct sizing and provides for correct interaction between the various components involved. The process is as follows:

1. Run DesignBuilder [Heating design](#) and [Cooling design](#) calculations in order to get the maximum heating and cooling loads for the system.
2. Choose/load a correctly sized water-to-water heat pump model from DesignBuilder database by matching the peak heating/cooling loads with heat pump's 'Rated heating/cooling capacity'. Or alternatively, creating and applying your own heat pump data if its catalogue data is available (using procedure described in the).
3. Select ground heat exchanger (vertical) borehole numbers from that quick/simple sizing table; set flow rate equal to the sum of 'Rated source side flow rate' of heat pumps connecting to it, or use your own tool to generate (and apply) a vertical ground heat exchanger case for specific conditions or detailed/precise sizing.
4. Condenser loop: set flow rate equal to or greater than the flow rate of ground heat exchanger (vertical) calculated above.

For more detail on these processes see the [GSHP Example](#).

What about the EnergyPlus ParameterEstimation model?

The EnergyPlus **ParameterEstimation** model limits the refrigerant used to R22 and the compressor to the reciprocating compressor type. However almost all water-to-water heat pumps presently on the market use refrigerants other than R22 (R22 has been phased out recently for environmental reasons) and equipped with scroll and other compressor types. So catalogue data is no longer available for the **ParameterEstimation** model.

Also EnergyPlus strongly recommend using the **EquationFit** model instead of **ParameterEstimation** for efficient and reliable modelling,

For these reasons DesignBuilder currently only provides the **EquationFit** water-to-water heat pump model.
Equation Fit Heat Pumps Technical

The Equation Fit model uses four non-dimensional equations or curves to predict the heat pump performance. The same method is used in both cooling and heating modes.

The performance data used in the Equation Fit method is derived from manufacturers data through a pre-process step in which the generalized least square method is used to generate a set of performance coefficients from manufacturer's catalogue data at indicated reference conditions. This is done in an EnergyPlus spreadsheet. Then the calculated coefficients and indicated reference conditions are entered on the heat pump dialog in the model to simulate the heat pump performance. A library of templates containing pre-defined manufacturers heat pump data is provided to allow an early stage analysis to be carried out without specific project equipment being specified.

The variables that influence the water-to-water heat pump performance include load side entering water temperature, source side entering water temperature, source side water flow rate and load side water flow rate. The governing equations for the cooling and heating modes are as follows:

Cooling Mode

$$\frac{Q_c}{Q_{c,ref}} = A1 + A2 \left[\frac{T_{L,in}}{T_{ref}} \right] + A3 \left[\frac{T_{S,in}}{T_{ref}} \right] + A4 \left[\frac{\dot{V}_L}{\dot{V}_{L,ref}} \right] + A5 \left[\frac{\dot{V}_S}{\dot{V}_{S,ref}} \right]$$

$$\frac{Power_c}{Power_{c,ref}} = B1 + B2 \left[\frac{T_{L,in}}{T_{ref}} \right] + B3 \left[\frac{T_{S,in}}{T_{ref}} \right] + B4 \left[\frac{\dot{V}_L}{\dot{V}_{L,ref}} \right] + B5 \left[\frac{\dot{V}_S}{\dot{V}_{S,ref}} \right]$$

Heating Mode:

$$\frac{Q_h}{Q_{h,ref}} = C1 + C2 \left[\frac{T_{L,in}}{T_{ref}} \right] + C3 \left[\frac{T_{S,in}}{T_{ref}} \right] + C4 \left[\frac{\dot{V}_L}{\dot{V}_{L,ref}} \right] + C5 \left[\frac{\dot{V}_S}{\dot{V}_{S,ref}} \right]$$

$$\frac{Power_h}{Power_{h,ref}} = D1 + D2 \left[\frac{T_{L,in}}{T_{ref}} \right] + D3 \left[\frac{T_{S,in}}{T_{ref}} \right] + D4 \left[\frac{\dot{V}_L}{\dot{V}_{L,ref}} \right] + D5 \left[\frac{\dot{V}_S}{\dot{V}_{S,ref}} \right]$$

Assuming no losses, the source side heat transfer rate for cooling and heating mode is calculated as:

$$Q_{source,c} = Q_c + Power_c$$

$$Q_{source,h} = Q_h - Power_h$$

Where:

A1-D5 EquationFit curve coefficients for the cooling and heating mode

T_{ref} Reference temperature (using fixed 283.15K)

$T_{L,in}$ Load side entering water temperature (K)

$T_{S,in}$ Source side entering water temperature (K)

$\dot{V}_L$ Load side volumetric flow rate (m3/s)

V_s Source side volumetric flow rate (m³/s)
 $V_{L,ref}$ Reference load side volumetric flow rate (m³/s)
 $V_{S,ref}$ Reference source side volumetric flow rate (m³/s)
 Q_c Load side heat transfer rate (cooling mode) (W)
 $Power_c$ Power consumption (cooling mode) (W)
 $Q_{source,c}$ Source side heat transfer rate (cooling mode) (W)
 Q_h Load side heat transfer rate (heating mode) (W)
 $Q_{h,ref}$ Reference load side heat transfer rate (heating mode) (W)
 $Power_h$ Power consumption (heating mode) (W)
 $Power_{h,ref}$ Reference power consumption (heating mode) (W)
 $Q_{source,h}$ Source side heat transfer rate (heating mode) (W)

Heat Pump - Cooling

General

Name

This field contains the unique identifying name for the cooling side of the plant loop heat pump.

Type

DesignBuilder provides the following plant loop heat pump types:

- [1-Equation fit water to water heat pump](#) - corresponds to the EnergyPlus Equation fit model.
- [2-Plant loop EIR heat pump](#) - for modelling water to water or air to water heat pumps based on the EIR formulation.

Tip: For both these heat pump types, it is important to use manufacturer's performance data to ensure the accuracy of your simulations.

Equation Fit Water to Water Heat Pump

The Equation fit model uses four non-dimensional equations (curves) to predict the heat pump performance in cooling and heating modes. The methodology involves using the generalised least square method to generate a set of performance coefficients from the catalogue data at indicated reference conditions. Then the respective coefficients and indicated reference conditions are used in the model to simulate the heat pump performance. The variables that influenced the water-to-water heat pump performance are load side inlet water temperature, source side inlet temperature, source side water flow rate and load side water flow rate.

General

Template

You can load data to the dialog from a pre-defined heat pump template as a starting point for your particular heat pump component. A sample list of manufacturers data is provided in the templates and instructions on how to create your own templates from manufacturers data.

Heat pumps are usually selected using their Rated cooling capacity.

Reference COP

This setting is required if the [Reference cooling power consumption](#) is set to autosize. The nominal COP is defined by the [Reference cooling capacity](#) divided by the corresponding Reference cooling power consumption and is non-dimensional. This field is only used for sizing; if the Reference power consumption is set to a fixed value then the COP of the component during simulation will be determined by the ratio of

Reference cooling capacity divided by the corresponding Reference cooling power consumption and not by the value in this field. This COP does not include power for fluid circulation pumps, it is just for the heat pump itself.

Sizing factor

This setting allows a sizing factor for this component to be specified. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. The Sizing factor allows a component to be sized to meet part of the plant loop's design load while continuing to use the autosizing feature. For example if there are two heat pumps on the supply side, each one could be sized to be half of the design load.

Rated Flow Rate And Capacity

Reference load side flow rate

This autosizable setting contains the rated volumetric flow rate on the load side of the heat pump in (m³/s or gal/min). This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Reference source side flow rate

This autosizable setting contains the rated volumetric flow rate on the source side of the heat pump in (m³/s or gal/min). This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Reference cooling capacity

This autosizable setting contains the rated cooling capacity of the heat pump in W. This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Reference cooling power consumption

This autosizable setting contains the rated power consumption of the heat pump in W. This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Performance Curves

Cooling capacity curve

Select a [Quad Linear](#) Performance curve to be used to define the cooling capacity of this heat pump at runtime.

More details on how these coefficients are used are provided in the [technical section](#) of the Plant loop heat pumps page and in the [Engineering Reference](#).

Cooling compressor power curve

Select a [Quad Linear](#) Performance curve to define the Cooling compressor power curve. More details on how these coefficients in the curve are used are described in the [Engineering Reference](#).

Companion Component

Companion heating heat pump

This optional selection allows you to specify the companion heating water to water heat pump for this cooling component. This should be the name of an Equation Fit heat pump heating component on the same plant loop. Because the cooling and heating models are often intended to represent separate operating modes of one single reversible heat pump, it is useful to identify the corresponding heating heat pump. This is used with autosizing so that the sizing calculations can be coordinated ensuring that the two companion heat pumps get the same design reference flow rates.

Plant loop EIR Heat Pump

The plant loop EIR model is based on the same formulation used in the EIR chiller model. This allows curves specifying capacity and energy usage to be defined generically, enabling them to be applicable to a wide variety of components. In this model, the curve can be a quadratic function of temperatures or an even more generic lookup table.

Tip: Note: The EIR model is more flexible than the Equation fit model. It can be operated either as a water-sourced heat pump with the source side connected to another plant loop or as an air-sourced heat pump with the source side interacting with the outdoor air.

Data for this component is also considered to be easier to obtain than for the Equation fit model.

Note: This component is currently a constant flow device (it will always request its full design flow from the plant). A future addition is planned to make it respond to outlet setpoint in order to vary the flow request.

General

Reference COP

This setting defines the reference COP for this unit, which is used when calculating the power required for the heat pump under simulation conditions. The COP is defined as the load side energy transfer divided by the power input, with dimensionless units of [W/W].

Sizing factor

This setting allows the sizing of this unit to be scaled relative to the plant-determined autosized flow and heat capacity.

Flow Rates And Capacity

Load side reference flow rate

This autosizable setting defines the reference load side flow rate for the heat pump. This field is used as the nominal flow request for this heat pump unit during the simulation. The units for this field are (m³/s or gal/min).

Source side reference flow rate

This autosizable setting defines the reference source side flow rate for the heat pump. This field is used as the nominal flow request for this heat pump unit during the simulation. The units for this field are (m³/s or gal/min).

Important Note: For *air source* heat pumps, the **Source side reference flow rate** is an air flow rate, whereas for *water to water* heat pumps it is a water flow rate. Water source side reference flow rates will typically be much lower than Air source reference air flow rates.

Reference capacity

This autosizable setting defines the heat pump's reference load side cooling capacity (in W).

Performance Curves

Capacity modifier function of temperature curve

Select a [Bivariate](#) curve or table that defines an available capacity modifier of the unit as a function of the load side outlet temperature and the source side inlet temperature. The temperatures are in °C when used in the function and the output of the function is multiplied by the reference capacity to get a current available capacity.

Electric input to output ratio modifier function of temperature curve

Select a [Bivariate](#) curve or table that defines an EIR (1/COP) modifier as a function of the load side outlet temperature and the source side inlet temperature. The temperatures are in °C when used in the function. The output of this function and the output of the EIR Modifier Function of PLR are multiplied by the reference EIR to get a current EIR .

Electric input to output ratio modifier function of part load ratio curve

Select a [Univariate](#) curve or table that defines an EIR modifier as a function of the current part load ratio. The output of this function and the output of the EIR Modifier Function of Temperature are multiplied by the reference EIR to get a current EIR .

Condenser

Condenser type

Select the heat pump's condenser type. Options are:

- **1-Air Source** - for an air to water heat pump
- **2-Water Source** for a water to water heat pump

Heat Pump - Heating

General

Name

This field contains the unique identifying name for the heating side of the plant loop heat pump.

Type

DesignBuilder provides the following plant loop heat pump types:

- [1-Equation fit water to water heat pump](#) - corresponds to the EnergyPlus Equation fit model.
- [2-Plant loop EIR heat pump](#) - for modelling water to water or air to water heat pumps based on the EIR formulation.

Tip: For both these heat pump types, it is important to use manufacturer's performance data to ensure the accuracy of your simulations.

Equation Fit Water to Water Heat Pump

The Equation fit model uses four non-dimensional equations (curves) to predict the heat pump performance in cooling and heating modes. The methodology involves using the generalised least square method to generate a set of performance coefficients from the catalogue data at indicated reference conditions. Then the respective coefficients and indicated reference conditions are used in the model to simulate the heat

pump performance. The variables that influenced the water-to-water heat pump performance are load side inlet water temperature, source side inlet temperature, source side water flow rate and load side water flow rate.

General

Template

You can load data to the dialog from a pre-defined heat pump template as a starting point for your particular heat pump component. A sample list of manufacturers data is provided in the templates and instructions on how to create your own templates from manufacturers data.

Heat pumps are usually selected using their Rated heating capacity.

Reference COP

This setting is used if the [Reference heating power consumption](#) is set to autosize. The nominal COP is defined by the Reference heating capacity divided by the corresponding Reference heating power consumption and is non-dimensional. This field is only used for sizing; if the Reference power consumption is set to a fixed value then the COP of the component during simulation will be determined by the ratio of Reference heating capacity divided by the corresponding Reference heating power consumption and not by the value in this field. This COP does not include power for fluid circulation pumps, it is just for the heat pump itself.

Sizing factor

This setting allows a sizing factor for this component to be specified. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. The Sizing factor allows a component to be sized to meet part of the plant loop's design load while continuing to use the autosizing feature. For example if there are two heat pumps on the supply side, each one could be sized to be half of the design load.

Rated Flow Rate And Capacity

Reference load side flow rate

This autosizeable setting contains the rated volumetric flow rate on the load side of the heat pump in (m³/s or gal/min). This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Reference source side flow rate

This autosizeable setting contains the rated volumetric flow rate on the source side of the heat pump in (m³/s or gal/min). This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Reference heating capacity

This autosizeable setting contains the rated heating capacity of the heat pump in W. This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Reference heating power consumption

This autosizeable setting contains the rated power consumption of the heat pump in W. This corresponds to the highest load side heat transfer rate listed in the catalogue data.

Performance Curves

Heating capacity curve

Select a [Quad Linear](#) Performance curve to be used to define the heating capacity of this heat pump at runtime.

More details on how these coefficients are used are provided in the [technical section](#) of the Water to water heat pumps page and in the [Engineering Reference](#).

Heating compressor power curve

Select a [Quad Linear](#) Performance curve to define the Heating compressor power curve. More details on how these coefficients in the curve are used are described in the [Engineering Reference](#).

Companion Component

Companion cooling heat pump

This optional selection allows you to specify the companion cooling water to water heat pump for this heating component. This should be the name of an Equation Fit heat pump cooling component on the same plant loop. Because the cooling and heating models are often intended to represent separate operating modes of one single reversible heat pump, it is useful to identify the corresponding cooling heat pump. This is used with autosizing so that the sizing calculations can be coordinated ensuring that the two companion heat pumps get the same design reference flow rates.

Plant loop EIR Heat Pump

The plant loop EIR model is based on the same formulation used in the EIR chiller model. This allows curves specifying capacity and energy usage to be defined generically, enabling them to be applicable to a wide variety of components. In this model, the curve can be a quadratic function of temperatures or an even more generic lookup table.

Tip: Note: The EIR model is more flexible than the Equation fit model. It can be operated either as a water-sourced heat pump with the source side connected to another plant loop or as an air-sourced heat pump with the source side interacting with the outdoor air.

Data for this component is also considered to be easier to obtain than for the Equation fit model.

Note: This component is currently a constant flow device (it will always request its full design flow from the plant). A future addition is planned to make it respond to outlet setpoint in order to vary the flow request.

General

Reference COP

This setting contains the reference COP for this unit, which is used when calculating the power required for the heat pump under simulation conditions. The COP is defined as the load side energy transfer divided by the power input, with dimensionless units of [W/W].

Sizing factor

This setting allows the the sizing of this unit to be scaled relative to the plant-determined autosized flow and heat capacity.

Flow Rates And Capacity

Load side reference flow rate

This autosizable setting defines the reference load side flow rate for the heat pump. This field is used as the nominal flow request for this heat pump unit during the simulation. The units for this field are (m3/s or gal/min).

Source side reference flow rate

This autosizable setting defines the reference source side flow rate for the heat pump. This field is used as the nominal flow request for this heat pump unit during the simulation. The units for this field are (m3/s or gal/min).

Important Note: For *air source* heat pumps, the **Source side reference flow rate** is an air flow rate, whereas for *water to water* heat pumps it is a water flow rate. Water source side reference flow rates will typically be much lower than Air source reference air flow rates.

Reference capacity

This autosizable setting defines the heat pump's reference load side heating capacity (in W).

Performance Curves

Capacity modifier function of temperature curve

Select a [Bivariate](#) curve or table that defines an available capacity modifier of the unit as a function of the load side outlet temperature and the source side inlet temperature. The temperatures are in °C when used in the function and the output of the function is multiplied by the reference capacity to get a current available capacity.

Electric input to output ratio modifier function of temperature curve

Select a [Bivariate](#) curve or table that defines an EIR (1/COP) modifier as a function of the load side outlet temperature and the source side inlet temperature. The temperatures are in °C when used in the function. The output of this function and the output of the EIR Modifier Function of PLR are multiplied by the reference EIR to get a current EIR .

Electric input to output ratio modifier function of part load ratio curve

Select a [Univariate](#) curve or table that defines an EIR modifier as a function of the current part load ratio. The output of this function and the output of the EIR Modifier Function of Temperature are multiplied by the reference EIR to get a current EIR .

Condenser

Condenser type

Select the heat pump's condenser type. Options are:

- **1-Air Source** - for an air to water heat pump
- **2-Water Source** for a water to water heat pump

Generating Heat Pump Coefficients From Manufacturers Data

In order to allow manufacturer's water-to-water and water-to-air heat pump catalogue data to be used, EnergyPlus have provided spreadsheets to generate heating/cooling capacity coefficients (1 to 5) and compressor power coefficients (1 to 5) for each heat pump model. The spreadsheets are available from the [EnergyPlus support desk](#), or from [DesignBuilder](#).

Processing Catalogue Data

The following briefly introduces how to use spreadsheets mentioned above to generate datasets in the required formats from manufacturers catalogue data.

Manufacturer's catalogues normally provides more data points than are needed to generate coefficients for the EnergyPlus heat pumps. The EnergyPlus spreadsheet only requires 7 fields:

1. i.e., source side entering water temperature (EWT),
2. source side flow rate,
3. load side EWT
4. load side flow rate,
5. output (heating/cooling output),
6. input (compressor power input) and
7. heat of extraction (HE in heating mode)/heat of rejection (HR in cooling mode).

These seven fields must be rearranged as columns in the order specified by the EnergyPlus spreadsheet before attempting to generate the relevant coefficients.

The more data points used, the more accurate the calculation of the coefficients. As EnergyPlus states, the minimum data points for EF based model are 5. However, the data points must involve various inlet conditions (e.g. water flow rates, inlet water temperatures, etc.) that cover the entire range of the heat pump operating conditions.

Some catalogue data is in IP units, however the EnergyPlus spreadsheets can take data in either SI or IP units (data in IP units will be converted to SI units after a button is clicked in the spreadsheets). All processing is carried out using SI units.

The figure below shows how the relevant catalogue data is rearranged to the format EnergyPlus spreadsheets require and how the links between the two are established starting with the manufacturer's table on the right table and copying relevant data to the spreadsheet shown on the left). The example is based on a Carrier heat pump model 50PSW180 heating mode .

Required input data table

Source EWT (deg-C)	Source flow rate (m3/s)	Load EWT (deg-C)	Load flow rate (m3/s)	Output (kW)	Input (kW)	HE (kW)

Reference Condition Explanation And EquationFit Functionality Verification

Using Carrier water-to-water heat pump model 50PSW036 (heating) sample data as an example, the figure below describes where the reference data used in equations is allocated. Applying coefficients and referenced data into equations, the heating output and power (electric) input figures can be calculated (two columns at the bottom of the figure). These calculated figures show a good consistency with original catalogue data, proving a working functionality of EquationFit model.

$$\frac{Q_h}{Q_{h,ref}} = C1 + C2 \left[\frac{T_{L,in}}{T_{ref}} \right] + C3 \left[\frac{T_{S,in}}{T_{ref}} \right] + C4 \left[\frac{\dot{V}_L}{\dot{V}_{L,ref}} \right] + C5 \left[\frac{\dot{V}_S}{\dot{V}_{S,ref}} \right]$$

$$\frac{Power_h}{Power_{h,ref}} = D1 + D2 \left[\frac{T_{L,in}}{T_{ref}} \right] + D3 \left[\frac{T_{S,in}}{T_{ref}} \right] + D4 \left[\frac{\dot{V}_L}{\dot{V}_{L,ref}} \right] + D5 \left[\frac{\dot{V}_S}{\dot{V}_{S,ref}} \right]$$

Model: Carrier 50PSW036-Heating; Rated heating output: 12.6kW; Rated power input: 2.8kW;
Rated source side flow rate: 0.00057m³/s; Rated load side flow rate: 0.00057m³/s.

 $T_{ref} = 283.15K$

Generated by EnergyPlus Spreadsheets using data in the table at top-left corner.

Good consistency between calculated heating capacity/electric power and original catalogue data.

Recommendation for efficient use when heating

The highest supply water temperature provided in catalogue data is normally between 50°C-60°C. This is not normally hot enough to supply hot water radiators and heating coils and you are advised not to connect to water radiators to these systems. However, EnergyPlus does not limit the output water temperature to the catalogue maximum, so in practice, if setpoints allow it, supply water temperatures can achieve the typical hot water radiator/baseboard temperature levels of 75°C-80°C. The figure below uses Carrier model 50PSW036 (highest leaving water temperature 51.8°C) heating as an example to show the impact of using heat pumps in this way. Extrapolation of catalogue data is not normally recommended however the trend line (following red coloured line) shows its COP value is much reduced at 1.38 when output water temperature reaches 80°C. So

this sort of system configuration is clearly not nearly as energy efficient as a low temperature system such as a heated floor which require supply temperatures around 35°C. Underfloor heating is therefore recommended for use with GSHP.

Ground Source Heat Pump (GSHP) Example

Create a building model first then follow the steps below to set up a water to water (ground source) heat pump (GSHP) system using vertical boreholes to provide both heating through heated floors and cooling through chilled beams.

Note: This example is currently based on using Equation fit heat pumps and has not yet been updated to use the more up date EIR heat pumps.

1. Run DesignBuilder Heating design calculation to obtain peak heating load.

Air Temperature (°C)	22.00
Radiant Temperature (°C)	18.59
Operative Temperature (°C)	20.30
Outside Dry-Bulb Temperature (°C)	-4.80
Glazing (kW)	-6.57
Walls (kW)	-2.88
Ground Floors (kW)	-0.28
Roofs (kW)	-7.07
External Infiltration (kW)	-26.03
External Vent. (kW)	-42.45
Zone Sensible Heating (kW)	85.15

Edit	Visualise	Heating design	Cooling design	Simulation	CFD	Daylighting	Cost and Carbon
------	-----------	----------------	----------------	------------	-----	-------------	-----------------

In this case, peak heating load is 85 kW.

2. Run DesignBuilder Cooling design calculation to obtain peak cooling load.

Edit	Visualise	Heating design	Cooling design	Simulation	CFD	Daylighting	Cost and Carbon
------	-----------	----------------	----------------	------------	-----	-------------	-----------------

In this case, (coincidentally) the peak cooling load is also 85 kW.

3. Create detailed HVAC system of ground source heat pump model.

The layout below shows a typical heating and cooling application. This was loaded from the **GSHP - Heated Floor and Chilled Beams** HVAC template but you can create a similar layout from scratch to suit your particular configuration.

4. Set heat pump heating component data.

Navigate to the Heat pump heating component and edit it. Load an appropriate heat pump template using the heat pump [Rated heating capacity](#) data to match the heat pump with the design heating load calculated in step 1. You can see in the example below a heat pump having 104.6 kW has been selected to meet the peak heating load of 85 kW giving some spare capacity.

Alternatively you can create your own heating capacity coefficients and heating compressor power coefficients together with rated flow rates, rated heating capacity and rated heating power consumption from catalogue data.

Note that the rated load side flow rate for the selected heat pump is 0.00442 m³/s.

	50	24	24	24	24	24	24	24	24	24	24
	60	24	24	24	24	24	24	24	24	24	40
	70	40	40	40	40	40	40	40	40	40	40
	80	40	40	40	40	40	40	40	40	40	40
	90	40	40	40	40	40	40	40	40	40	40
	100	40	40	40	40	40	40	40	40	40	40

Change both **Design flow rate** and **Maximum flow rate** to 0.00884 which is the sum of 0.00442 + 0.00442 for the heat pump heating and heat pump cooling components respectively. Refer to steps 4 and 5. If you have used your own specific heat pump heating/cooling data generated from catalogue data you should alter this flow rate figure accordingly.

Ground heat exchanger - vertical

Quick/Simple sizing

Generally, there is a quick/simple way in doing ground loop heat exchanger sizing. The procedure is to use DesignBuilder 'Heating Design' and 'Cooling Design' calculations to obtain peak heating and cooling loads in kW, then look at the table below to get a minimum borehole number for the model.

		Peak cooling load (kW)									
		10	20	30	40	50	60	70	80	90	100
Peak heating load (kW)	10	4	4	8	8	8	12	12	12	16	16
	20	8	8	8	12	12	12	12	12	16	16
	30	12	12	12	12	16	16	16	16	16	16
	40	16	16	16	16	16	24	24	24	24	24
	50	24	24	24	24	24	24	24	24	24	24
	60	24	24	24	24	24	24	24	24	24	40
	70	40	40	40	40	40	40	40	40	40	40
	80	40	40	40	40	40	40	40	40	40	40
	90	40	40	40	40	40	40	40	40	40	40
	100	40	40	40	40	40	40	40	40	40	40

Recommended flow rate for ground heat exchanger is the maximum of sum of rated flow rates from all connected heat pumps for heating or heat pumps for cooling.

Detailed/Precise sizing

The net heating or cooling of the ground over each season clearly depends on the accumulated heat rejection/extraction, and therefore on the building loads throughout the whole year (not only the peak loads mentioned above), which might be available through simulation based on a very simple HVAC setting in DesignBuilder.

The solution for above relies on using other ground loop heat exchanger tools (not supplied by DesignBuilder or EnergyPlus), which are capable of doing detailed/precise sizing.

Load vertical ground heat exchanger data from a file

When using vertical ground heat exchanger, you can load settings and g-functions from idf files stored on your local drive.

7. Set condenser loop flow rate.

Change **Maximum loop flow rate** from **Autosize** to 0.00884, the same as (or greater than) ground heat exchanger flow rate, derived in step 6.

Important note: You must not use Autosize for condensers connected to GSHPs.

Condenser Loop

The Condenser loop consists of:

- Supply sub loop which contains one or more cooling towers, a pump and a setpoint controller
- Demand sub loop which distributes the water to the condenser of a water-cooled chiller.

This dialog covers the sizing and operation details of the overall loop.

Load Distribution Scheme

The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. There are 3 options:

- 'Sequential' uses each piece of equipment to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand.
- 'Optimal' operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand.
- 'Uniform' evenly distributes the loop demand amongst all available components on the equipment list for a given load range.

Help Cancel OK

8. Turn on ground floor's internal source in order to apply underfloor heating system.

Edit any Ground floor, Internal floor or External floor constructions where the underfloor heating applies to ensure that an internal source is included in the construction.

To ensure the best heat transfer from the embedded hot water pipes to the room occupied region, the innermost layer (top layer) of the construction should have a relatively small thickness using thermally conductive timber flooring or tiles rather than a more insulating material such as carpet.

On the [Internal source](#) tab, check the [Internal source](#) option and assign the position of the internal source within the construction layers. The internal source layer should normally be placed at one layer below (inside) innermost layer.

9. Run simulation and check the results.

(1) Summer modelling results:

During occupied hours each day in summer, room air temperature was controlled well at 24°C (cooling setpoint temperature is 24°C).

(2) Winter modelling results:

During occupied hours each day in winter, room air temperature was controlled at about 23°C (heating setpoint temperature is 22°C).

Air To Water Heat Pump / ASHP Data

The air to water heat pump, aka air source heat pump (ASHP), is a compound object consisting of a [water heater](#) tank, [a direct expansion \(DX\) "coil"](#) (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source.

Note: The terms "Water heater heat pump", "Air to water heat pump", "Air source heat pump" and "ASHP" are used interchangeably in the documentation.

Various configurations of tank location, inlet air source, and DX coil compressor location can be modelled.

Air to water heat pumps can be added in 2 main locations:

1. Supply side of an auxiliary heating loop.
2. Supply side of DHW loop.

- As a zone object within an HVAC zone. In this case the inlet air source is the zone in which the Water heater heat pump is located.

The heat pump's DX coil is the primary heat source and the water tank's heater (element or burner) can provide supplemental heat as necessary. The model also assumes that the heat pump's fan and water pump cycle on and off with the compressor.

The components making up the air to water heat pump are:

- Water heater heat pump is the top level object. The data for the dialog is described below.
- [Water heater](#) - used to store hot water generated by the heat pump coil. The tank can be used to represent a buffer tank and the volume set .
- Air to water heat pump coil
- On/off fan

The ASHP HVAC template uses a more sophisticated way to combine ASHP and supplementary heating. The ASHP provides the main heating and a hot water loop with boiler is used to provide any additional heat required to meet the overall supply setpoint via a heat exchanger .

Example HVAC layout showing how an ASHP can be supplemented by heat from a hot water loop

General

Name

Enter a unique name for the air to water heat pump.

Availability schedule

The availability [schedule](#) defines the times when the heat pump compressor is available to operate. A schedule value equal to 0 denotes that the heat pump compressor is off for that time period. A value other than 0 denotes that the heat pump compressor is available to operate during that time period. During times when the heat pump compressor is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the heat pump's parasitic electric power is also off for that time period.

Compressor Settings

Compressor setpoint temperature schedule

This [schedule](#) defines the set point (or “cut-out”) temperature for the heat pump compressor. Temperature values used in this schedule should be in degrees Celsius. The heat pump compressor cycles off when the tank water reaches this set point temperature. Once the heat pump compressor cycles off, the tank water temperature drops until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the “cut-in” temperature). At this point, the heat pump compressor cycles on and remains on until the heat pump compressor set point temperature is reached.

Important Note: The overall heat pump compressor “cut-in” temperature (**Compressor setpoint temperature schedule** value minus the [dead band temperature difference](#) below) must be greater than the [Water Heater Setpoint temperature schedule](#) (“cut-out” temperature) in order for the heat pump to provide heat to the water heater tank.

Dead band temperature difference

This numeric field contains the dead band temperature difference (in °C or °F). The heat pump compressor “cut-in” temperature is defined as the **Compressor set point temperature** defined above minus this dead band temperature difference. The heat pump compressor cycles on when the water temperature in the tank falls below the “cut-in” temperature. The heat pump compressor remains on until the water temperature in the tank rises above the compressor set point (“cut-out”) temperature defined above. The dead band temperature difference must be greater than 0°C and less than or equal to 20°C.

In this model, the heat pump water heater’s DX compression system is considered the primary heat source and the water tank’s heater (element or burner) provides supplemental heat as necessary. Therefore, the cut-in temperature for the heat pump compressor (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the heat pump compressor, the heat pump compressor is disabled and the tank’s heater is used to heat the water.

Minimum inlet air temperature for compressor operation

This numeric field contains the minimum inlet air dry-bulb temperature entering the air coil (evaporator) and fan section (in °C or °F) below which the heat pump compressor does not operate. The minimum inlet air dry-bulb temperature should be greater than or equal to -20°C.

Note: The minimum **Minimum inlet air temperature for compressor operation** setting allowed in DesignBuilder is -20°C, but if you intend to export the model to run outside DesignBuilder in EnergyPlus v8.6, the minimum temperature allowed is higher at -5°C. In this case, if you need to use a value lower than -5°C, you should either copy the idd file stored in the DesignBuilder EnergyPlus folder to the EnergyPlus folder you are using, or manually edit the EnergyPlus idd file. In EnergyPlus v8.9 and later, the minimum limit has been removed so this issue will not arise.

Compressor location

Select the location of the heat pump compressor and the air temperature for this location used to control operation of the compressor’s crankcase heater in the [Air to water heat pump coil](#). Valid entries are:

- **1-Schedule**, in which case a compressor ambient temperature schedule must be defined below.
- **2-Zone** when the crankcase heater operation is controlled based on the air temperature in the zone in which the ASHP is located.
- **3-Outdoors** in which case the crankcase heater operation is controlled based on the outdoor air temperature.

The **2-Zone** option is only available when the ASHP is used as an object placed within an HVAC zone.

Compressor ambient temperature schedule

This schedule is available when the **1-Schedule** option is selected as the Compressor location above. It defines the ambient air temperature surrounding the heat pump compressor, which is used to control the compressor's crankcase heater operation.

Flow Rate Settings

Condenser water flow rate

This numeric field contains the heat pump's condenser water flow rate (in m3/s or gal/min). It is the actual condenser water flow rate to be simulated, which may differ from the [Rated condenser water flow rate](#) specified for the heat pump's DX coil. This water flow rate must be greater than 0 or this field is autoc calculatable. If autocalculated (field value = autocalculate), the condenser water flow rate is set equal to the rated heating capacity of the heat pump's DX coil multiplied by 4.487E-8 m3/s/W. When this flow rate is different from the [Rated condenser water flow rate](#) specified for the heat pump's DX coil, the user should also specify a [Heating capacity function of water flow fraction curve](#) and a [Heating COP function of water flow fraction curve](#) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated water flow rate.

Evaporator air flow rate

This numeric field contains the air flow rate across the heat pump's air coil (evaporator) (in m3/s or ft3/min). It is the actual air flow rate to be simulated, which may differ from the [Rated evaporator air flow rate](#) specified for the heat pump's DX coil. Values must be greater than 0 or this field is autoc calculatable. If autocalculated (field value = autocalculate), the evaporator air flow rate is set equal to the rated heating capacity of the heat pump's DX coil multiplied by 5.035E-5 m3/s/W. When this flow rate is different from the [Rated evaporator air flow rate](#) specified for the heat pump's DX coil, the user should also specify a [Heating capacity function of air flow fraction curve](#) and a [Heating COP function of air flow fraction curve](#) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated water flow rate.

Inlet Air Settings

Inlet air configuration

Select the configuration of the air flow path through the heat pump air coil (evaporator) and fan section. Valid entries are:

- **1-Schedule**, in which case names an inlet air temperature schedule and an inlet air humidity schedule are defined in the fields below.
- **2-Zone air only**, option only available when the ASHP is placed as a zone unit. The inlet air is sourced from the zone in which the ASHP is placed.
- **3-Outdoor air only**.
- **4-Zone and outdoor air**, option only available when the ASHP is placed as a zone unit. The inlet air is sourced from the zone in which the ASHP is placed and mixed with outdoor air based on the [Inlet air mixer schedule](#) below.

Inlet air temperature schedule

Select the schedule used to define the dry-bulb temperature of the inlet air to the heat pump air coil (evaporator) and fan section. Schedule values should be in degrees Celsius. This field is only required when the [Inlet air configuration](#) defined above is specified as **1-Schedule**.

Inlet air humidity schedule

Select the schedule used to define the humidity of the inlet air to the heat pump evaporator and fan section. Schedule values must be entered as relative humidity fraction from 0 to 1 (e.g., a schedule value of 0.5 means 50%RH). This field is only required when the [Inlet air configuration](#) defined above is specified as **1-Schedule**.

Inlet air mixer schedule

If the **Inlet air configuration** is specified as **4-Zone and outdoor air** you must select the Inlet air mixer schedule which defines whether the heat pump draws its inlet air from the zone, outdoors, or a combination of zone and outdoor air. A schedule value equal to 0 indicates that the heat pump draws its inlet air from the zone. A schedule value equal to 1 denotes that the heat pump draws its inlet air from outdoors. Values between 0 and 1 denote a mixture of zone and outdoor air proportional to the schedule value. The **Inlet air mixer schedule** controls both the inlet air mixer and outlet air splitter nodes in unison to ensure that the operation of the heat pump does not contribute to zone pressurization or depressurization. For example if the Inlet air mixer schedule value is 0.4, then the inlet air mixer node is composed of 40% outdoor air and 60% zone air. For this same case, the outlet air splitter directs 60% of the ASHP outlet air back to the zone and 40% of the outlet air flow is exhausted outdoors.

Fan Settings

Fan placement

This Selection defines the placement of the fan in the heat pump water heater. Valid choices are:

- **1-Blow through** (fan upstream of the air coil) and
- **2-Draw through** (fan downstream of the air coil).

Parasitic Load Settings

On cycle parasitic electric load

This numeric field contains the on-cycle parasitic electric power (in W). This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump water heater. This parasitic electric load is consumed whenever the heat pump compressor is operating and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., **Inlet air configuration** field specified as **2-Zone air only**, or **4-Zone and outdoor air**) and the **Parasitic heat rejection location** field is specified as **1-Zone**. The minimum value for this field is 0.0, and the default value is also 0.0.

Off cycle parasitic electric load

This numeric field contains the off-cycle parasitic electric power (in W). This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump compressor. This parasitic electric load is consumed whenever the heat pump water heater is available but the compressor is not operating, and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., **Inlet air configuration** field specified as **2-Zone air only**, or **4-Zone and outdoor air**) and the **Parasitic heat rejection location** field is specified as **1-Zone**. The minimum value for this field is 0.0, and the default value is also 0.0.

Parasitic heat rejection location

Select where the on-cycle and off-cycle parasitic heat is rejected. Valid choices are:

- **1-Zone** where both the on-cycle and off-cycle parasitic heat is rejected to the zone. This option is only available for ASHP used as zone equipment in which case the heat is rejected to the zone containing the ASHP.
- **2-Exterior** where parasitic heat is rejected outdoors (does not impact the zone air heat balance)

Air To Water Heat Pump Coil

The Air To Water Heat Pump "Coil" described here models an air-to-water DX compression system (which includes a water heating coil, air coil, compressor, and water pump) to determine its air-side and water-side

performance. It is used within the composite EnergyPlus [air to water heat pump](#) which also includes a [water heater](#) tank and a [fan](#) to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source.

This DX coil calculates the air-side sensible and latent cooling capacity at the specific operating conditions for each simulation timestep, as well as the condenser's water-side temperature difference at a given condenser water flow rate. The heat pump water heater DX coil model performs the following major functions:

- Calculates the electric consumption of the DX compressor and water pump.
- Calculates the amount of heat delivered to the water tank.
- Calculates the electric consumption of the compressor's crankcase heater.
- Calculates the air-side performance of the DX coil.

The input fields for this object are described below in detail.

General

Name

Enter a unique name for the air to water heat pump coil.

Rated heating capacity

This numeric field defines the DX coil heating capacity (in W or Btu/h) at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below. Values must be greater than 0. This value represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field [Condenser pump heat included in rated heating capacity and rated COP](#) below).

Rated COP

This numeric field defines the DX coil's water heating coefficient of performance ($COP = \text{water heating capacity} / \text{electrical power input}$) at rated conditions (rated inlet temperatures and flow rates specified below). This input not only determines the electric energy use of the heat pump DX coil, but also the amount of total air cooling provided by the evaporator. The rated COP includes compressor power, and may or may not include condenser pump power or evaporator fan power (see field [Evaporator fan power included in rated COP](#) and field [Condenser pump power included in rated COP](#)). Values must be greater than 0.

Rated sensible heat ratio

This numeric field defines the air-side sensible heat ratio ($SHR = \text{sensible cooling capacity} / \text{total cooling capacity}$) of the DX coil at rated conditions (rated inlet temperatures and flow rates specified below). This value should not include the effect of evaporator fan heat. Values must be greater than or equal to 0.5, and less than or equal to 1.0. The default value is 0.85.

Evaporator Settings

Rated evaporator inlet air dry-bulb temperature

This numeric field defines the evaporator inlet air dry-bulb temperature (in °C or °F), that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5°C. The default value is 19.7°C.

Rated evaporator inlet air wet-bulb temperature

This numeric field defines the evaporator inlet air wet-bulb temperature (in °C or °F) that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5°C. The default value is 13.5°C.

Rated evaporator air flow rate

This numeric field defines the evaporator air volume flow rate (m³/s or ft³/min) at rated conditions. Values must be greater than 0. If this field is autocalculated (value = autocalculate), the default value is 5.035E-5 m³/s/W (31.25 cfm/MBH) multiplied by the [Rated heating capacity](#) specified above. When autocalculating the rated evaporator air volumetric flow rate, the zone sizing data is not used.

Evaporator fan power included in rated COP

This choice field specifies if evaporator fan power is included in the rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If this option is selected, the evaporator fan power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. Otherwise it is assumed that the total heating power does not include evaporator fan power. See the Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Condenser Settings

Rated condenser inlet water temperature

This numeric field defines the condenser inlet water temperature (in °C or °F) that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 25°C. The default value is 57.5°C.

Rated condenser water flow rate

This numeric field defines the condenser water volumetric flow rate (in m³/s or gal/min) at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (value = autocalculate), the default value is 4.487E-8 m³/s/W (0.208 gpm/MBH) multiplied by the [Rated heating capacity](#) specified above. When autocalculating the rated condenser water volumetric flow rate, the data in the zone sizing object is not used. A warning message will be issued if the ratio of [Rated condenser water flow rate](#) to [Rated heating capacity](#) is less than 1.79405E-8 m³/s/W (0.083 gpm/MBH) or greater than 8.97024E-8 m³/s/W (0.417 gpm/MBH), but the simulation will continue.

Condenser pump power included in rated COP

This option specifies whether condenser pump power is included in the rated COP defined above. This input impacts the calculation of compressor electric power which then impacts the total air cooling provided by the evaporator for each simulation timestep. If it is selected, the condenser pump power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. Otherwise it is assumed that the total heating power does not include the condenser pump. See Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Condenser pump heat included in rated heating capacity and rated COP

This option specifies whether condenser pump heat is included in the rated heating capacity and rated COP defined above. It impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If it is selected, the condenser pump heat is already included in the rated heating capacity and rated COP. If it isn't selected, it is assumed that the rated heating capacity and rated COP do not include the condenser pump heat, and pump heat is added to the total water heating capacity based on the [Condenser water pump power](#) and [Fraction of condenser pump heat to water](#) fields below. See Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Condenser water pump power

This numeric field defines the DX coil's condenser pump power (in W or Btu/h). This is the operating pump power as installed. Values must be greater than or equal to 0. A warning message will be issued if the ratio of [Condenser water pump power](#) to [Rated heating capacity](#) exceeds 0.1422 W/W (41.67 Watts/MBH), but the simulation will continue.

Fraction of condenser pump heat to water

This numeric field defines the fraction of condenser pump heat that is transferred to the condenser water. The pump is assumed to be downstream of the condenser water coil, and this field is used to determine the water temperature at the condenser outlet node when the [Condenser pump power included in rated heating capacity and COP](#) option is unchecked. Values must be greater than or equal to 0 and less than or equal to 1. The default value is 0.2.

Crankcase Heater Settings

Crankcase heater capacity

This numeric field defines the compressor's crankcase heater capacity (in W or Btu/h). The crankcase heater only operates when the compressor is off and the air surrounding the compressor is below the [Maximum ambient temperature for crankcase heater operation](#) specified below.

Maximum ambient temperature for crankcase heater operation

This numeric field defines the maximum ambient temperature for crankcase heater operation (in °C or °F). The crankcase heater only operates when the air surrounding the compressor is below this maximum temperature value and the compressor is off. The ambient temperature surrounding the compressor is set by the Air to water heat pump parent object ([Compressor location](#)).

Performance Settings

You can use curves to modify the rated capacity and rated COP defined above based on one or more performance curves. To apply a curve first check its associated check box and then select the required curve.

Note: to use the rated capacity and rated COP without modification you should uncheck all of the check boxes in this section.

Evaporator air temperature type for curves

This drop list selection specifies the air temperature type used for the heating capacity and COP modifier curve objects below. The valid selections are:

- **1-Dry-bulb temperature** in which case the inlet air dry-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects.
- **2-Wet-bulb temperature** where the inlet air wet-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects.

If the curves are not defined then this field is not used.

Heating capacity function of temperature curve

This [Bi-quadratic](#) or [Cubic](#) performance curve defines the variation in DX coil heating capacity as a function of inlet fluid (air and water) temperatures. The Bi-quadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field [Evaporator air temperature type for curves](#) defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated heating capacity to give the heating capacity at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures.

If the associated checkbox is unchecked, the heating capacity remains constant (curve value assumed to be 1.0 for all conditions).

Heating capacity function of air flow fraction curve

This [Quadratic](#) or [Cubic](#) performance curve defines the variation in DX coil heating capacity as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the Rated heating capacity and the Heating capacity modifier curve (function of temperature) to give the DX coil heating capacity at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0).

If the associated checkbox is unchecked the heating capacity remains constant (curve value assumed to be 1.0 for all air flow rates).

Heating capacity function of water flow fraction curve

This [Quadratic](#) or [Cubic](#) performance curve defines the variation in DX coil heating capacity as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied by the rated heating capacity and the output from the two other heating capacity modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating capacity at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0).

If the associated checkbox is unchecked the heating capacity remains constant (curve value assumed to be 1.0 for all water flow rates).

Heating COP function of temperature curve

This [Bi-quadratic](#) or [Cubic](#) performance curve defines the variation in DX coil heating COP as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field [Evaporator air temperature type for curves](#) defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated COP to give the heating COP at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures.

If the associated checkbox is unchecked the COP remains constant (curve value assumed to be 1.0 for all conditions).

Heating COP function of air flow fraction curve

This [Quadratic](#) or [Cubic](#) performance curve defines the variation in DX coil heating COP as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated COP and the heating COP modifier curve (function of temperature) to give the heating COP at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0).

If the associated checkbox is unchecked the heating COP remains constant (curve value assumed to be 1.0 for all air flow rates).

Heating COP function of water flow fraction curve

This [Quadratic](#) or [Cubic](#) performance curve defines the variation in DX coil heating COP as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied by the rated COP and the output from the two other heating COP modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating COP at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0).

If the associated checkbox is unchecked the heating COP remains constant (curve value assumed to be 1.0 for all water flow rates).

Part load fraction correlation curve

This [Quadratic](#) or [Cubic](#) performance curve parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq \text{PLR} < 1$), the following rules apply:

$\text{PLF} \geq 0.7$ and $\text{PLF} \geq \text{PLR}$

If $\text{PLF} < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $\text{PLF} < \text{PLR}$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Air To Water Heat Pump Example

This example explains the main steps involved in setting up an ASHP system. It involves loading an ASHP Detailed HVAC template and modifying some settings to achieve a high-performance low temperature ASHP system with gas-fired boiler supplementary heating.

The steps are as follows.

1. Create a new file located in London Gatwick and add a building to the site with a simple square block having dimensions 10m x 10m. Use default Model options and template settings.

Note: Although this example is based on a simple single zone building model, you could follow the same steps on your own multi-zone model.

2. Set the [Detailed HVAC](#) model option.
3. Load the [ASHP Air-to-water Heat Pump, Supplementary Boiler, Water Convectector](#) Detailed HVAC template to the occupied zone(s).

This provides an air to water heat pump with gas boiler supplementary heater which provides high temperature water.

4. Run the [Heating design calculations](#) to obtain the total heating [Design Capacity](#) for the building and hence the required heating capacity of the ASHP system.

5. Edit the [Air to water heat pump coil](#)

5.1. Change the default high temperature model loaded from the template to use low temperature outlet from the HP. To do this, change the heating capacity and COP function of temperature performance curve settings as follows:

- Change [Heating capacity function of temperature curve](#) to **ASHP LowT COPFT**, and
- Change [Heating COP function of temperature curve](#) to **ASHP LowT Heating CAPFT**.

The curves section of the dialog should now be similar to the screenshot below.

5.2. Enter the [Rated heating capacity](#) of the ASHP. Enter 90% of the design heating load calculated in step 4. The system will rely on the gas boiler to boost overall system capacity to achieve the full capacity.

5.3. To ensure that the rated conditions are consistent with the new curves selected in step 5.1, you should change the [Rated evaporator inlet air dry and wet-bulb temperatures](#) to 16°C and 12°C respectively. See below.

Evaporator Settings	
Rated evaporator inlet air dry-bulb temperature (°C)	16.00
Rated evaporator inlet air wet-bulb temperature (°C)	12.00
Rated evaporator air flow rate (m3/s)	Autocalculate

6. Next move up a level in the HVAC system hierarchy and edit the [Air to water heat pump](#) (Water heater heat pump) and:

- Create and select a new schedule to set the water outlet temperature setpoint to be 58°C. To do that duplicate **LowT heat pump water supply temperature: Always 55.00** to create **LowT heat pump water supply temperature: Always 58.00**. Apply the new schedule to the [Compressor setpoint temperature schedule](#) field.
- Ensure that the [Minimum inlet air temperature for compressor operation](#) is set to -10°C to allow operation on cold days but prevent operation on days colder than -10°C.
- Change the [Deadband temperature difference](#) to 2°C.

7. Edit the [Water heater](#) and verify some key inputs:

- On the **Water heater** tab, ensure that the [Tank volume](#) is set to **Autosize**.
- On the **Sizing** tab, check that [Design mode](#) is set to **1-Peak draw** and the [Time for tank recovery](#) is set to 0.6hr.

9. Edit the [Boiler](#) and change the capacity of the boiler to provide the remaining 10% of the design heating load.

10. Check that the [SPM](#) downstream of the supply side of the HX controls the supply water temperature to 55°C.

11. Change the Pressure rise of the [ASHP fan](#) to 100Pa.

12. Finally, run a simulation of the model over the winter to ensure that the overall system is able to meet the heating loads even on the coldest days without excessive use of the supplementary gas-fired boiler. You should see results similar to those shown below.

Note how the gas boiler only needs to fire on the coldest periods.

District Heating

Used in:

- Hot water loop, supply side

The district heating component is used to provide heat to the supply side of a hot water loop. It can be used to model these systems:

- a. Centralised sources of hot water (district heating systems), or,
- b. Cases where it is not necessary to simulate the plant., e.g. where the focus of the study is on the air side of the system or the building zones.

General

Name

The auto-generated name of the district cooling system can be edited.

Nominal capacity

This numeric field contains the nominal demand (in W or Btu/h) that the district heating will meet. This field is autosizable.

Capacity fraction schedule

Select the schedule that describes how the nominal capacity varies over time. Values must non-negative. The capacity at a given point in time is determined by the product of the **Nominal capacity** (above) and the value in this schedule. The default schedule is **On 24/7** i.e. a value of 1 all the time.

Performance Curves

Curve:Linear

Curve:QuadLinear Used in many HVAC components as well as electrical storage devices

Curve:DoubleExpon

entialDecay

In EnergyPlus HVAC, performance curves are the mathematical mechanism that adjusts rated equipment performance (capacity, efficiency, airflow effects, etc.) as operating conditions change based on actual operating conditions. They are needed because most HVAC equipment does not operate at its rated capacity or efficiency except at laboratory reference conditions. In more detail, performance curves:

- Modify capacity, efficiency and other equipment characteristics based on temperatures, flow rates etc.
- Capture part-load performance and cycling losses.
- Apply manufacturer catalogue data to allow real equipment to be modelled.
- Allow generalised HVAC component models to behave like specific real equipment.

DesignBuilder performance curves consist of a range of different polynomial curve types that are used to characterise the performance of HVAC equipment. Several other non-polynomial curves are also included to characterize the performance of pumps and fans. The curves are usually derived from fits or regressions to data covering a limited range. Results for independent variable values outside this range are likely to be invalid, so curve input always contains a range of validity (maximum and minimum permitted values) for each independent variable and can optionally have limits on the curve output. No error or warning message is issued if an independent variable is outside the range. Instead, EnergyPlus uses the minimum value if an independent variable is less than the minimum, and the maximum if a variable exceeds the maximum. Similarly, no error or warning message is issued if the curve output is outside the range of the optional minimum and maximum curve output limits. Instead, EnergyPlus uses the minimum and maximum curve limits to cap the output of the performance curve.

Tip: For guidance on how to generate the data required for Performance curves see: "Performance Curve Coefficient Tools" on page 916

General Tab

On the **General** tab you can set the curve type and enter the curve coefficients.

The curve data follow a similar pattern and all have the same first 4 data items:

Name

A user assigned unique name for a curve. When a curve is used, it is referenced by this name.

Note

Specific information about the curve.

Source

The source setting defines the origin of the curve. For most library curves provided with the software, the source is usually either "EnergyPlus", meaning it comes from the EnergyPlus curves database, which is largely derived from the DOE-2 database, or "DesignBuilder" meaning that the curve is provided by DesignBuilder Software.

Category

The category can be one of:

- [Linear](#)
- [Quad Linear](#)
- [Quint Linear](#)
- [Quadratic](#)
- [Cubic](#)
- [Exponent](#)
- [Bi-Quadratic](#)
- [Bi-Cubic](#)
- [Quartic](#)
- [Rectangular Hyperbola 2](#)
- [Double Exponential Decay](#)

The rest of the data depends on the curve **Category** setting, as described below.

Linear

Input for the linear curve consists of a curve name, the two coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g. limit extrapolation). The equation represented by the linear curve is:

$$y = C_1 + C_2 * x$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 x

The linear coefficient (C_2) in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Quad Linear

Input consists of the curve name, the five coefficients, and maximum and minimum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is represented by this curve:

$$y = C_1 + C_2 * w + C_3 * x + C_4 * y + C_5 * z$$

Name

A user assigned unique name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Coefficient2 w

The coefficient (C_2) in the equation.

Coefficient3 x

The coefficient (C_3) in the equation.

Coefficient4 y

The coefficient (C_4) in the equation.

Coefficient5 z

The coefficient (C_5) in the equation.

MinimumW

The minimum allowable value of w. Values of w less than the minimum will be replaced by the minimum.

MaximumW

The maximum allowable value of w. Values of w greater than the maximum will be replaced by the maximum.

MinimumX

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

MaximumX

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

MinimumY

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

MaximumY

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

MinimumZ

The minimum allowable value of z. Values of z less than the minimum will be replaced by the minimum.

MaximumZ

The maximum allowable value of z. Values of z greater than the maximum will be replaced by the maximum.

Input unit type for W

This field is used to indicate the kind of units that may be associated with the w values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of w** and **Maximum value of w**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for X

This field is used to indicate the kind of units that may be associated with the x values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for Y

This field is used to indicate the kind of units that may be associated with the y values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of y** and **Maximum value of y**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for Z

This field is used to indicate the kind of units that may be associated with the z values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of z** and **Maximum value of z**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Quint Linear

Input consists of the curve name, the six coefficients, and maximum and minimum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is represented by this curve:

$$y = C_1 + C_2 * v + C_3 * w + C_4 * x + C_5 * y + C_6 * z$$

Name

A user assigned unique name for an instance of this curve. When a curve of this type is used, it is referenced by this name.

Coefficient1 Constant

The constant coefficient (C_1) in the equation.

Coefficient2 v

The coefficient (C_2) in the equation.

Coefficient3 w

The coefficient (C_3) in the equation.

Coefficient4 x

The coefficient (C_4) in the equation.

Coefficient5 y

The coefficient (C_5) in the equation.

Coefficient6 z

The coefficient (C_6) in the equation.

MinimumV

The minimum allowable value of v. Values of v less than the minimum will be replaced by the minimum.

MaximumV

The maximum allowable value of v. Values of v greater than the maximum will be replaced by the maximum.

MinimumW

The minimum allowable value of w. Values of w less than the minimum will be replaced by the minimum.

MaximumW

The maximum allowable value of w. Values of w greater than the maximum will be replaced by the maximum.

MinimumX

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

MaximumX

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

MinimumY

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

MaximumY

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

MinimumZ

The minimum allowable value of z. Values of z less than the minimum will be replaced by the minimum.

MaximumZ

The maximum allowable value of z. Values of z greater than the maximum will be replaced by the maximum.

Input unit type for V

This field is used to indicate the kind of units that may be associated with the v values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of v** and **Maximum value of v**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for W

This field is used to indicate the kind of units that may be associated with the w values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of w** and **Maximum value of w**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for X

This field is used to indicate the kind of units that may be associated with the x values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**

- **5-Distance**
- **6-Power**

Input unit type for Y

This field is used to indicate the kind of units that may be associated with the y values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of y** and **Maximum value of y**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input Unit Type for Z

This field is used to indicate the kind of units that may be associated with the z values. It is used by the editor to display the appropriate SI and IP units for the **Minimum value of z** and **Maximum value of z**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Quadratic

Input for a quadratic curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g. limit extrapolation). The equation represented by the quadratic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 x

The linear coefficient (C_2) in the equation.

Coefficient 3 x²

The quadratic coefficient (C_3) in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Cubic

Input for a cubic curve consists of the curve name, the 4 coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g. limit extrapolation). The equation represented by the cubic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2 + C_4 * x^3$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 x

The linear coefficient (C_2) in the equation.

Coefficient 3 x²

The quadratic coefficient (C_3) in the equation.

Coefficient 4 x³

The quadratic coefficient (C_4) in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Exponent

Input for a exponent curve consists of the curve name, the 3 coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g. limit extrapolation). The equation represented by the exponent curve is:

$$y = C_1 + C_2 * x^{C_3}$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 constant

The linear coefficient (C_2) in the equation.

Coefficient 3 constant

The exponent coefficient (C_3) in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Bi-quadratic

This curve is a function of two independent variables. Input consists of the curve name, the six coefficients, and min and max values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g. limit extrapolation). The equation represented by the biquadratic curve is:

$$z = C_1 + C_2 * x + C_3 * x^2 + C_4 * y + C_5 * y^2 + C_6 * xy$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 x

The linear coefficient (C_2) in the equation.

Coefficient 3 x^2

The quadratic coefficient (C_3) in the equation.

Coefficient 4 y

The coefficient C_4 in the equation.

Coefficient 5 y^2

The coefficient C_5 in the equation.

Coefficient 6 xy

The coefficient C_6 in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum value of y

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

Maximum value of y

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of x** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for y

This field is used to indicate the kind of units that may be associated with the y values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of y** and **Maximum value of y**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Bi-cubic

This curve type is a function of two independent variables. Input consists of the curve name, the ten coefficients, and the minimum and maximum values for each of the independent variables. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g. limit extrapolation). The equation represented by the bicubic curve is:

$$z = C_1 + C_2 * x + C_3 * x^2 + C_4 * y + C_5 * y^2 + C_6 * xy + C_7 * x^3 + C_8 * y^3 + C_9 * x^2y + C_{10} * xy^2$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 x

The linear coefficient (C_2) in the equation.

Coefficient 3 x^2

The quadratic coefficient (C_3) in the equation.

Coefficient 4 y

The coefficient C_4 in the equation.

Coefficient 5 y^2

The coefficient C_5 in the equation.

Coefficient 6 xy

The coefficient C_6 in the equation.

Coefficient 7 x^3

The coefficient C_7 in the equation.

Coefficient 8 y^3

The coefficient C_8 in the equation.

Coefficient 9 x^2y

The coefficient C_9 in the equation.

Coefficient 10 xy^2

The coefficient C_{10} in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum value of y

The minimum allowable value of y. Values of y less than the minimum will be replaced by the minimum.

Maximum value of y

The maximum allowable value of y. Values of y greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by editor to display the appropriate SI and IP units for the **Minimum value of X** and **Maximum value of x**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Input unit type for y

This field is used to indicate the kind of units that may be associated with the y values. It is used by editor to display the appropriate SI and IP units for the Minimum Value of y and Maximum Value of y. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**

- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Quartic

Input for a Quartic (fourth order polynomial) curve consists of the curve name, the five coefficients, and the maximum and minimum valid independent variable values. Optional inputs for curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation represented by the quartic curve is:

$$y = C_1 + C_2 * x + C_3 * x^2 + C_4 * x^3 + C_5 * x^4$$

Coefficient 1 constant

The constant coefficient (C_1) in the equation.

Coefficient 2 x

The linear coefficient (C_2) in the equation.

Coefficient 3 x^2

The quadratic coefficient (C_3) in the equation.

Coefficient 4 x^3

The cubic coefficient (C_4) in the equation.

Coefficient 5 x^4

The fourth-order coefficient (C_5) in the equation.

Minimum value of x

The minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum curve output

The minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum value of x

The maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This field is used to indicate the kind of units that may be associated with the x values. It is used by IDF Editor to display the appropriate SI and IP units for the Minimum Value of X and Maximum Value of x. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select Dimensionless which will have no unit conversion.

- **1-Dimensionless**
- **2-Temperature**
- **3-VolumetricFlow**
- **4-MassFlow**
- **5-Distance**
- **6-Power**

Output unit type

This field is used to indicate the kind of units that may be associated with the output values. It is used by the editor to display the appropriate SI and IP units for the **Minimum curve output** and **Maximum curve output**. The unit conversion is not applied to the coefficients. The available options are shown below. If none of these options are appropriate, select **1-Dimensionless** which will have no unit conversion.

- **1-Dimensionless**
- **2-Capacity**
- **3-Power**

Rectangular Hyperbola 2

Input for the single rectangular hyperbola type 2 curve consists of the curve name, the three coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve minimum and maximum may be used to limit the output of the performance curve (e.g., limit extrapolation). The equation is:

$$y = (C_1 * x) / (C_2 + x) + C_3 * x$$

Coefficient 1 C_1

The required numeric constant coefficient C_1 in the equation.

Coefficient 2 C_2

The required numeric constant coefficient C_2 in the equation.

Coefficient 3 C_3

The required numeric constant coefficient C_3 in the equation.

Minimum value of x

The required numeric minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum.

Maximum value of x

The required numeric maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum.

Minimum curve output

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum.

Maximum curve output

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

This optional field is provided for future purposes so that DesignBuilder could display the appropriate SI or IP units for the **Minimum value of x** and **Maximum value of x** (currently dimensionless). At this time, only the Dimensionless option is provided so that no unit conversion is used for this curve.

Output unit type

This optional field is provided for future purposes so that DesignBuilder could display the appropriate SI or IP units for the **Minimum curve output** and **Maximum curve output** (currently dimensionless). At this time, only the **1-Dimensionless** option is provided so that no unit conversion is used for this curve.

Double Exponential Decay

Input for the double exponential decay curve consists of the curve name, the five coefficients, and the maximum and minimum valid independent variable values. Optional inputs for the curve include the minimum and maximum output of the performance curve. The equation is:

$$y = C_1 + C_2 \exp(C_3 x) + C_4 \exp(C_5 x)$$

Coefficient 1 C_1

The required numeric constant coefficient C_1 in the equation.

Coefficient 2 C_2

The required numeric constant coefficient C_2 in the equation.

Coefficient 3 C_3

The required numeric constant coefficient C_3 in the equation.

Coefficient 4 C_4

The required numeric constant coefficient C_4 in the equation.

Coefficient 5 C_5

The required numeric constant coefficient C_5 in the equation.

Minimum value of x

The required numeric minimum allowable value of x. Values of x less than the minimum will be replaced by the minimum

Maximum value of x

The required numeric maximum allowable value of x. Values of x greater than the maximum will be replaced by the maximum

Minimum curve output

The optional numeric minimum allowable value of the evaluated curve. Values less than the minimum will be replaced by the minimum

Maximum curve output

The optional numeric maximum allowable value of the evaluated curve. Values greater than the maximum will be replaced by the maximum.

Input unit type for x

The optional field is provided for future purposes so that DesignBuilder could display the appropriate SI or IP units for the **Minimum** and **Maximum value of x**. Currently, only Dimensionless option is provided so that no unit conversion is used for this curve

Output unit type

The optional field is provided for future purposes so that DesignBuilder could display the appropriate SI or IP units for the **Minimum** and **Maximum curve output**. Currently, only the **1-Dimensionless** option is provided so that no unit conversion is used for this curve.

Curve Plot Tab

Click on the **Curve Plot** tab to view the performance curve data in graphical form.

Performance Curve Coefficient Tools

A range of tools are available to help set up performance curves in a form that can be used in DesignBuilder EnergyPlus simulations based on equipment manufacturers' data sheets:

- **DesignBuilder Curve Generator Tool:** Accessed from the Info panel of the Curves dialog.
- **VRF Curve Generation Utilities:** Specialised spreadsheet tools for generating EnergyPlus curves for accurate variable refrigerant flow (VRF) system simulation.
- **EnergyPlus Curve Fit Tool:** Used to generate HVAC performance curve coefficients for any HVAC equipment modelled with Biquadratic, Cubic, or Quadratic curves using manufacturer data sheets.
- **Chiller Performance Curve Coefficients Tool:** Used to generate performance curve coefficients for chillers and any other HVAC equipment modelled with Biquadratic, Cubic, or Quadratic curves using manufacturer data sheets.
- **Ice Storage Curve Fit Tool:** Assists with generating performance curve coefficients for Ice Thermal Storage charge and discharge cycles.

All of the above are freely available utilities for generating performance curve coefficients used in HVAC equipment modelling within DesignBuilder/EnergyPlus. They enable users to input performance data at various operating conditions and automatically generate the polynomial coefficients needed to create the curves for accurate equipment simulation. They are commonly used for chillers, heat pumps, DX coils, fans, pumps, and other HVAC equipment.

Notes on the "Chiller Performance Curve Coefficients" and the "EnergyPlus Curve Fit" Tools

Both these tools provided by EnergyPlus generate the same curve types (Biquadratic, Cubic, and Quadratic) using identical mathematical principles. Each tool is optimised for its primary workflow, but both offer flexibility for adaptation. Neither tool is strictly limited to a single equipment type or medium (e.g., chillers, heat pumps, air-source vs water-source systems, or water pumps).

Both tools are flexible enough to allow you to adapt the independent variable inputs to match your equipment's actual operating conditions. For example, you can adjust the labels and input ranges to represent water temperatures rather than air temperatures, making them suitable for water-to-water systems. See unmet hours article: <https://unmethours.com/question/2059/air-source-heat-pump-curves>. You can also generate the cubic curves required for water pump part-load performance modelling.

Fundamentally, the labels are simply examples tied to the tools' original design intent, while the mathematical curve fitting capability is what makes them generally applicable. Once this principle is clear, you can use either tool (or any other available) for any application requiring Biquadratic, Cubic, or Quadratic curve fitting, regardless of the specific equipment type or operating medium.

For more information on all performance curve types, see: [Performance Curve Data](#).

How DesignBuilder Plots Performance Curves

From the Curves dialog, you can view the performance data as graphical curves on the [Curve Plot](#) tab of the dialog.

When DesignBuilder plots a performance curve, the axes and legend representation depends on whether the curve is single-variable or multi-variable:

Single-variable curves (e.g., Linear, Quadratic, Cubic, Quartic):

- Horizontal axis (X): The independent variable (e.g., part-load ratio, flow fraction, temperature)
- Vertical axis (Output): The curve's output value (e.g., power modifier, efficiency modifier)

BG Shaft Power Curve

Multi-variable curves (e.g., Biquadratic, Bicubic):

- Horizontal axis (X): The first independent variable (e.g., leaving chilled water temperature)
- Legend entries (Y, colored lines): The second independent variable held constant for each series (e.g., outdoor/source temperature at different fixed values)
- Vertical axis (Output): The curve's output value (e.g., EIR modifier, capacity modifier)

The variable assignment is determined by the order in which you enter your independent variables in the Performance Curve Coefficients tool input table.

For example, when using the **DesignBuilder Curve Generator**:

- Column x (first variable) → Horizontal axis (X)
- Column y (second variable) → Legend (Y)

The screenshot shows the "Curve Generator Tool for DesignBuilder" window. It features two main tables for data entry. The left table has columns for x, y, Value, and Adjusted Value. The right table has columns for Coefficient and Value. Below the tables are several control elements: buttons for "Save Curve File", "Clear Table", "Open Curve File", and "Paste from SpreadSheet"; a checkbox labeled "Remove worst outlier data point"; a dropdown menu currently set to "BiQuadratic" which displays the equation $z = c_1 + c_2x + c_3x^2 + c_4y + c_5y^2 + c_6xy$; buttons for "About", "Calculate", and "Copy to DB"; a "Normalize by:" label followed by a text box containing the value "1"; and a "Copy Clipboard" button. The window title bar includes standard minimize, maximize, and close icons.

Note: Changing the minimum and maximum ranges of X and Y in the Edit Curve will not change which variable is assigned to the horizontal axis or the legend. This only changes the range over which those variables are evaluated.

Example: Chiller EIR Modifier For Temperature Curve (Biquadratic)

For a typical chiller Energy Input Ratio (EIR) modifier curve as a function of two temperatures, consider an example where you have performance data at various leaving chilled water temperatures and entering condenser water temperatures. This section demonstrates both how the plot appears in DesignBuilder and

how the coefficient generation is validated across the **Curve Generator** and **Chiller Performance Curve Coefficients** tools.

When modelling a chiller's EIR performance, you need to capture how its efficiency changes with:

- First independent variable (x): Supply/Leaving water temperature (CWS)
- Second independent variable (y): Entering condenser water temperature (ECT)
- Value (z) = EIR = 1/COP

EIR modifier as a function of temperature: $z = C_1 + C_2 \cdot x + C_3 \cdot x^2 + C_4 \cdot y + C_5 \cdot y^2 + C_6 \cdot x \cdot y$

You collect performance data at various combinations of these temperatures and enter them into the performance curve tool (e.g., Curve Generator or Chiller_PerformanceCurve_Coefficients) with their corresponding normalised EIR values (relative to rated conditions).

Capacity rated (kW)	Capacity (kW)	CWS (°C)	ECT (°C)	Power Input (kW)	EIR

78.6	90.6	18	45	37.7	0.41611479

Note: The performance curve tools require that your input data be normalised by dividing the performance value at each condition by the reference/nominal value (e.g., actual EIR / rated EIR). This normalisation is essential because it ensures the resulting curve has a value of 1.0 at reference conditions, which is how DesignBuilder/EnergyPlus interprets the curve during simulation. In **Curve Generator** this can be done by entering the reference value in the **Normalize by** field.

How to Generate Curves Using the Curve Generator

1. Open the **Curve Generator tool** in DesignBuilder, accessed from the Info panel of the **Curves** dialog.
2. Select **BiQuadratic** from the **Curve Category** dropdown
3. In the input data table, enter:
 - x column: Leaving chilled water temperatures (e.g., 5, 7, 10, 15, 18°C)
 - y column: Entering condenser water temperatures (e.g., 25, 30, 35, 40, 45°C)
 - Value column: Corresponding EIR values at each x, y combination
4. In the **Normalize by** field, enter the reference EIR value (e.g., if rated COP = 2.71, then reference EIR = $1/2.71 = 0.369$)
5. Click on the **Calculate** button to generate the coefficients
6. The tool in the right panel displays:
 - Six biquadratic coefficients (c1 through c6). These correspond to the biquadratic curve equation:

$$z = c1 + c2 \cdot x + c3 \cdot x^2 + c4 \cdot y + c5 \cdot y^2 + c6 \cdot x \cdot y$$
 - The minimum and maximum x and y values based on the input data range
 - R² value showing goodness-of-fit
7. Click the **Copy to DB** button to prepare for pasting the coefficients to the DesignBuilder Curve Editor, or **Save Curve File** for later entry, or **Copy to Clipboard** to paste the coefficients to a spreadsheet.

How to Generate Curves Using the Chiller Performance Curve Coefficients Tool

1. Open the **Chiller Performance Curve Coefficients** spreadsheet tool
2. In the performance data table, enter:
 - CAP_NOM (kW): Rated capacity
 - CAP (kW): Actual capacity at each condition
 - CWS (°C): Leaving chilled water temperatures (e.g., 5, 7, 10, 15, 18°C)
 - ECT (°C): Entering condenser water temperatures (e.g., 25, 30, 35, 40, 45°C)
 - UNIT RATE (kW): Power input
 - Rated EIR: The EIR in nominal conditions
3. The spreadsheet calculates the performance metrics: EIR(Normalized), EIR(Normalized EIR_predicted), COP, and EIR.
4. In the "Coefficients for the Energy Input Ratio Function of Temperature curve (EIRFT)" table, the tool displays:

- The calculated coefficient values labelled as (a, b, c, d, e, f). These correspond to the standard biquadratic form coefficients in the equation:

$$z = a + b \cdot x + c \cdot x^2 + d \cdot y + e \cdot y^2 + f \cdot x \cdot y$$
- R² value showing goodness-of-fit
- Other statistical measures from the regression

How to Enter Curve Coefficients into DesignBuilder and View the Curve Plot

Once you have generated the coefficients using either tool, you need to enter them into DesignBuilder to use them in your simulation:

1. Navigate to the Detailed HVAC system
2. Select the HVAC component (e.g., [Chiller](#), [Plant Loop Heat Pumps](#))
3. Go to the Performance Curves section
4. Create a copy of an existing Curve or add a new one.
5. Edit the Curve to enter the performance curve coefficients
6. Click the [Curve Plot](#) tab to visualize the curve

Example "Energy Input Ratio Modifier Function of Temperature Curve":

- Create a copy of an existing Curve or add a new one and name it "Example EIR Modifier Function of Temperature Curve"
- Open the Curve editor
- In the Curve editor choose the appropriate Curve type (e.g., Bi-Quadratic) and enter/paste the coefficients
- Set the curve Range (these should match your xmin, xmax, ymin, ymax values from the Performance Curve Coefficients Tools)

Edit Curve - Example EIR Modifier Function of Temperature Curve

Performance curves

EnergyPlus performance curves are generally polynomials that are used to characterize the performance of HVAC equipment. One other non-polynomial curve is also included to characterize the performance of pumps and fans.

The curves are usually derived from fits or regressions to data covering a limited range. Results for independent variable values outside this range are likely to be invalid, so curve input always contains a range of validity (maximum and minimum permitted values) for each independent variable and can optionally have limits on the curve output. No error or warning message is issued if an independent variable is outside the range. Instead, the curve manager uses the minimum value if an independent variable is less than the minimum, and the maximum if a variable exceeds the maximum. Similarly, no error or warning message is issued if the curve output is outside the range of the optional minimum and maximum curve output limits. Instead, the curve manager uses the minimum and maximum curve limits to cap the output of the performance curve.

What you will see in the DesignBuilder [Curve Plot](#) tab:

- Horizontal axis: Supply water temperatures (e.g., 5°C to 18°C representing leaving water temperature)
- Legend: Outdoor/condenser temperature held constant for each curve (e.g., Y=25, Y=30, Y=35, Y=40, Y=45 representing entering condenser water)
- Vertical axis: The curve output (e.g., EIR modifier value)

Each coloured line shows the multiplier (e.g. EIR multiplier) at different leaving water temperatures while holding the entering condenser water temperature constant. For example, the green line (Y=25°C) shows how EIR varies as leaving chilled water temperature changes from 5°C to 18°C when the condenser temperature is at 25°C.

Important Checks When Using Any Performance Curve Coefficients Tool

To ensure accurate curve generation, always verify the following:

1. Column Order and Axis Assignment

Ensure each independent variable in your dataset is mapped to the proper axis. The order of your columns determines which variable appears where on the plot:

- Check that your first independent variable corresponds to what should be on the horizontal axis
- Check that your second independent variable corresponds to what should be in the legend

- Refer to DesignBuilder documentation or the [EnergyPlus Input/Output Reference](#) to confirm the expected variable order for your specific curve type

2. Normalisation Value

Enter the correct reference value to normalise the curve output. Normalisation is essential for ensuring that the curve has a value of 1.0 at reference conditions. This value depends on both the curve type and the equipment being modelled.

Why this matters: If you enter the wrong normalisation value, your curve will not equal 1.0 at reference conditions, which will cause simulation errors or incorrect equipment performance predictions. DesignBuilder/EnergyPlus uses the curve output of 1.0 at reference conditions as the baseline for scaling equipment performance during simulation. The specific reference value to use (e.g., rated capacity, reference EIR) should be determined based on your equipment data and curve type.

Additional Information

For additional information, refer to the following documentation:

3. [Chiller:Electric:EIR Technical Description](#) - Detailed technical description of chiller EIR model and its performance curves
4. [EnergyPlus Documentation](#) - You can download all the EnergyPlus documentation from here
5. [Unmet Hours Article: Determine COP Performance Curves in DesignBuilder for an ASHP](#) - Community discussion on generating and validating heat pump performance curves

EnergyPlus Curve Fit Tool

The EnergyPlus Curve Fit spreadsheet Tool can be used to generate HVAC performance curves in EnergyPlus curve object format. For each set of performance data entered, Capacity and EIR performance curves are generated, and these curves are generated either as a function of temperature(s) or flow fraction. The Capacity and EIR of Cooling DX Coils as a function of temperatures require only Biquadratic curve whereas Capacity and EIR of Heating DX Coils may use Biquadratic, Cubic and Quadratic curves. The selection of either of these curves is dependent on availability of performance data. The Capacity and EIR as a function of flow fraction allows either Cubic or Quadratic curve type.

The curve coefficients calculated by the tool can be copied over manually into the relevant DesignBuilder dialogs.

Note: The curve fit spreadsheet can typically be found in a folder like **C:\EnergyPlusV23-1-0\PreProcess\HVACCurveFitTool** after installing the standalone version of EnergyPlus.

The curve types allowed are:

Cooling Capacity as a Function of Temperatures: Biquadratic Curve
 $cCapacity = a0 + a1*X + a2*X^2 + a3*Y + a4*Y^2 + a5*X*Y$

Heating Capacity as a Function of Temperatures: Biquadratic curve
 $hCapacity = a0 + a1*X + a2*X^2 + a3*Y + a4*Y^2 + a5*X*Y$

Heating Capacity as a Function of Temperatures: Cubic Curve
 $hCapacity = a0 + a1*X + a2*X^2 + a3*x^3$

Energy Input Ratio (EIR) as a Function of Temperatures: Biquadratic Curve

$$\text{EIR} = a_0 + a_1 \cdot X + a_2 \cdot X^2 + a_3 \cdot Y + a_4 \cdot Y^2 + a_5 \cdot X \cdot Y$$

Energy Input Ratio (EIR) as a Function of Temperatures: Cubic Curve

$$\text{EIR} = a_0 + a_1 \cdot X + a_2 \cdot X^2 + a_3 \cdot x^3$$

Capacity as a Function of Flow Fraction: Cubic Curve

$$\text{EIR} = a_0 + a_1 \cdot X + a_2 \cdot X^2 + a_3 \cdot x^3$$

Capacity as a Function of Flow Fraction: Quadratic Curve

$$\text{EIR} = a_0 + a_1 \cdot X + a_2 \cdot X^2$$

Energy Input Ratio (EIR) as a Function of Flow Fraction: Cubic Curve

$$\text{EIR} = a_0 + a_1 \cdot X + a_2 \cdot X^2 + a_3 \cdot x^3$$

Energy Input Ratio (EIR) as a Function of Flow Fraction: Quadratic Curve

$$\text{EIR} = a_0 + a_1 \cdot X + a_2 \cdot X^2$$

These performance curves as a function of temperatures are generated for a given set of input data at a given speed. The curves as a function of flow fraction are generated at the rated temperature conditions. The rated test condition is the AHRI standard rated test condition. The AHRI standard test condition may vary by the equipment type. For multiple speeds or multiple stage DX Coils, different curve sets can be generated by entering a different set of data for each speed or stage at a time. This tool can generate the following four curve types: (1) Capacity as a function of temperatures, (2) Capacity as a function of flow fraction, (3) EIR as a function of temperatures, and (4) EIR as a function of flow fraction. The tool automatically populates the labels for each data inputs variable when users select the Coil Type, Independent Variables, Curve Type, and Units as shown on INPU tab. The labels shown in the INPU tab are selected for DX Coil to generate capacity and EIR biquadratic curves as function of temperatures. The tool can be used for the DX coil types: Coil:Cooling:DX:SingleSpeed, Coil:Heating:DX:SingleSpeed, Coil:Cooling:DX:TwoSpeed (high and low speed) , CoilPerformance:DX:Cooling (each stage), and any HVAC equipment that use Biquadratic, Cubic or Quadratic curves. To add this flexibility generic input data labels can be populated by selecting "Other" for DX Coil Type input field, located in Cell B3 in the INPUT tab.

Editing Zone Group Data

Zone group data can be accessed as follows:

- [General](#) tab, where the building zones to be included in the zone group are selected.
- [Heating and Cooling Sequence](#) tab where the order of simulation is defined for each item of zone equipment.
- [Zone defaults](#) tab which is hidden by default but can be displayed when the [Show HVAC zone default data on the HVAC zone group dialog](#) Program option is selected.

See the [HVAC zone groups and components](#) tutorial

See also [Understanding HVAC Zone Groups](#).

General Tab

Title

This is the name that you assign to the zone group. The name must be unique and if a duplicate name is entered, the software will automatically append an integer in order to ensure a unique name.

Zones in Group

This is a tree control with checkboxes that you can use to define which building zones are to be added to the zone group. Only zones that have not already been assigned to other zone groups or plenums are made available for selection.

Tip: You can use the checkboxes at building and block levels as a fast way to select/deselect all of the available zones in the building or block.

Heating And Cooling Calculation Sequence Tab

Heating and cooling sequences are used to specify the order in which items of equipment are simulated by EnergyPlus in order to satisfy a heating or cooling load. Select a value of 1 against the system that should be simulated first. In the example below for a DOAS air system and a FCU, the Direct air ADU has been set up to be calculated before the FCU to ensure that any loads introduced by the fresh air can be met by the FCU.

Heating Calculation Sequence		
Block1:Zone1 Fan Coil Unit	2	
Block1:Zone1 Direct Air	1	
Cooling Calculation Sequence		
Block1:Zone1 Fan Coil Unit	2	
Block1:Zone1 Direct Air	1	

If the calculation sequence had been set up the other way round then the FCU is unlikely to have been able to accurately meet heating and cooling setpoints since it would not be accounting for the load introduced by the ADU.

Note 1: The heating and cooling calculation sequence can only be assigned after equipment has been added to one of the constituent HVAC zones.

Note 2: When a Zone group includes both heating and/or cooling zone equipment with an ADU providing ventilation air, DesignBuilder will by default set up the calculation sequence so that the air system is simulated first and other zone equipment after that. This will generally be the correct setting as mentioned above, it ensures that any air load resulting from the supply of centrally delivered air to the zone can be met by the other zone equipment. However you can change that behaviour manually by selecting zone equipment to simulate first.

Zone Defaults

When the [Show HVAC zone default data on the HVAC zone group dialog](#) Program option is selected you can enter default settings which will be used to initialise any HVAC zones *subsequently added* to this HVAC zone group. Making changes to these zone defaults values do not affect HVAC zones once they have been created.

Tip: The most important application of HVAC zone group default data is when [saving HVAC templates](#) where specific HVAC zone settings are required. Any HVAC zone settings made in the source model are not saved with an HVAC template, but the settings on the HVAC zone group are saved and applied to zones added to the HVAC zone group when the template is subsequently loaded in the destination model.

Editing HVAC Zone Data

Zone data is divided using 3 tabs:

- [General](#)
- [Sequence](#)
- [Target](#)

The [General tab](#) is used to define temperature and humidity control together with zone sizing information (Cooling Sizing, Heating Sizing and Outdoor Air Sizing). The [Cooling sizing](#) and [Heating sizing](#) information provides the data needed to perform a zone design air flow calculation for a single zone. This calculation assumes a variable amount of supply air at a fixed temperature and humidity. The information needed consists of the zone inlet supply air conditions: temperature and humidity ratio for heating and cooling.

The calculation is done for every design day included in the input. The maximum cooling load and air flow and the maximum heating load and air flow are then saved for the system level design calculations and for the component automatic sizing calculations. The [Outdoor air sizing](#) information is used to define the design outdoor air flow rate. This can be specified in a number of ways as described under [Outdoor air method](#). This data is then used in the EnergyPlus system sizing calculation for sizing zone components that use outside air. You can also place limits on the heating and design cooling air flow rates. See [Heating design air flow method](#) and [Cooling design air flow method](#) and the explanations of the various heating and cooling flow input fields.

See also:

- The [Sequence](#) tab
- The [Target tab](#) is used to specify which other zones in the zone group the changes will be applied to.
- [Autosizing HVAC Components](#)

Edit HVAC Zone Data - General Tab

Data on this tab is used for controlling the zone internal conditions during the simulation and also for autosizing heating, cooling and outside air equipment related to the zone.

General

Name

This is the name of the building zone with which the current HVAC zone is linked.

Thermostat Schedules

Detailed HVAC Activity data set to **2-Detailed HVAC**

If the **2-Detailed HVAC** [Detailed HVAC Activity data](#) model option is set then you can select schedules defining zone heating and cooling setpoint temperatures on this dialog. Otherwise, if the **1-Simple HVAC** option is selected then zone setpoint temperatures and schedules are defined on the Activity and HVAC model data tabs respectively and the Thermostat schedule data is not displayed on this dialog.

Note: The temperatures defined in these schedules must be in °C regardless of whether you are using [IP](#) or [SI](#) units in the interface.

Thermostat heating setpoint schedule

This is the zone heating temperature schedule. Values in the schedule are temperatures (in °C).

Thermostat cooling setpoint schedule

This is the zone cooling temperature schedule. Values in the schedule are temperatures (in °C).

Comfort PMV Setpoint Schedules

Detailed HVAC Activity data set to **2-Detailed HVAC**

If the **2-Detailed HVAC** [Detailed HVAC Activity data](#) model option is set then you can select schedules which define zone heating and cooling setpoint [PMV values](#) on this dialog. Otherwise, if the **1-Simple HVAC** option is selected then zone setpoint PMV values and schedules are defined on the Activity and HVAC model data tabs respectively and the Thermostat schedule data is not displayed on this dialog.

The [Thermal comfort calculator tool](#) can be used to derive PMV values based on perhaps more familiar parameters.

Heating PMV setpoint schedule

This is the zone heating PMV schedule. Values in the schedule are PMV indices, typically in the range -3 to 3.

Cooling PMV setpoint schedule

This is the zone cooling PMV schedule. Values in the schedule are PMV indices, typically in the range -3 to 3.

Humidistat Control

Humidistat control

This check-box is used to specify whether or not the zone has humidity control.

Detailed HVAC Activity data is **1-Simple HVAC**

If the **1-Simple HVAC** option is selected then zone RH setpoints on the Activity tab are used and the demand schedule data on this dialog defines the times when these setpoints operate.

Humidifying demand schedule

This is a schedule that defines the times when humidification may be required. The schedule should have only values of 0 (for times when no humidification is required) or 1 (when humidification to the humidification setpoint defined on the Activity tab is required).

Dehumidifying demand schedule

This is a schedule that defines the times when dehumidification may be required. The schedule should have only values of 0 (for times when no dehumidification is required) or 1 (when dehumidification to the dehumidification setpoint defined on the Activity tab is required).

Detailed HVAC Activity data is **2-Detailed HVAC**

If the **2-Detailed HVAC** [Detailed HVAC Activity data](#) model option is set then you can select schedules defining zone relative humidity setpoints on this dialog.

Humidifying RH setpoint schedule

This is a schedule that defines the humidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation.

Dehumidifying RH setpoint schedule

This is a schedule that defines the dehumidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation.

More information on controlling humidity is available in the [Humidity control](#) section.

The rest of the General tab of the HVAC Zone dialog is related to [Detailed HVAC autosizing](#) calculations only.

CO2 And Contaminant Control

CO2 and contaminant control

This check-box is used to specify whether or not the zone has CO2 or contaminant control. This must be selected if the zone is to have maximum CO2 or generic contaminant concentration controlled through one of the IAQP DCV methods.

Note: When the AHU DCV [System outdoor air method](#) has been set to one of **1-Zone sum**, **2-Standard 62.1 Ventilation Rate Procedure (VRP)** or **3-Standard 62.1 ventilation rate procedure with limit** then this option **must not be selected**.

Note: When one of the proportional DCV [System outdoor air methods](#) is selected on the AHU dialog (**5-Proportional control based on design occupancy**, **6-Proportional control based on occupancy schedule** or **9-Proportional control based on design outdoor air rate**) then selection of the **CO2 and contaminant control** checkbox on this dialog is optional. If you wish to specify zone minimum CO2 concentration settings for proportional control then you should check this checkbox, otherwise leave it unchecked, in which case outdoor air CO2 concentration will be used as the minimum instead. You can find details of the calculations used to calculate the target indoor CO2 concentration in the [Engineering reference](#) under Proportional Control.

Note: When one of the IAQP DCV [System outdoor air methods](#) are selected (**4-Indoor Air Quality Procedure (IAQP)** or **7-Indoor Air Quality Procedure (IAQP) generic contaminant**) then the **CO2 and contaminant** option must be selected for at least one HVAC zone connected to the AHU.

More information on DCV is available in the [DCV control](#) section of the AHU help page.

Detailed HVAC Activity data is 1-Simple HVAC

If the **1-Simple HVAC** option is selected then fixed contaminant setpoints from the Activity tab are used and no further data needs to be entered here.

Detailed HVAC Activity data is 2-Detailed HVAC

If the **2-Detailed HVAC** [Detailed HVAC Activity data](#) model option is set then you can select schedules defining time-varying CO2 and contaminant setpoints on this dialog.

CO2 control availability schedule

This is a schedule that defines the availability of CO2 control for each timestep of the simulation.

CO2 setpoint schedule

This is a schedule that defines the CO2 setpoint in ppm, for each timestep of the simulation.

Minimum CO2 concentration schedule

This is a schedule that defines the minimum concentration of CO2 in ppm, for each timestep of the simulation.

Generic contaminant control availability schedule

This is a schedule that defines the availability of Generic contaminant control for each timestep of the simulation.

Generic contaminant setpoint schedule

This is a schedule that defines the Generic contaminant setpoint in ppm, for each timestep of the simulation. Enter values between 0 and 1.

The rest of the General tab of the HVAC Zone dialog is related to [Detailed HVAC autosizing](#) calculations only.

Zone Air Distribution Effectiveness

ASHRAE Standard 62.1 defines Zone air distribution effectiveness (Ez) as a measure of how effectively the zone air distribution system uses the supply air to maintain acceptable air quality in the occupied zone (also known as the breathing zone). In an imperfect system the fresh air introduced through supply diffusers may not mix fully with the rest of the room air before being extracted. These settings allow the distribution effectiveness to be defined separately for heating and cooling operation modes.

Method

You can choose to either define fixed zone air distribution effectiveness values for heating and cooling or select a schedule with time-varying values to cover both heating and cooling together. Select from:

- **1-Separate heating and cooling** where fixed zone air distribution effectiveness values are entered separately for heating and cooling.
- **2-Scheduled** where a schedule is selected which defines how the zone air distribution effectiveness for both heating and cooling varies with time.

Effectiveness in cooling mode

Enter the fixed zone air distribution effectiveness when the zone is in cooling mode. ASHRAE Standard 62.1-2010 provides typical values (see table below). The default value 1.0.

Effectiveness in heating mode

Enter the fixed zone air distribution effectiveness when the zone is in heating mode. ASHRAE Standard 62.1-2010 provides typical values (see table below). The default value 1.0.

Zone Air Distribution Effectiveness (TABLE 6-2 ASHRAE 62.1)	
Air Distribution Configuration	Ez
Ceiling supply of cool air.	1.0
Ceiling supply of warm air and floor return.	1.0
Ceiling supply of warm air 15°F (8°C) or more above space temperature and ceiling return.	0.8
Ceiling supply of warm air less than 15°F (8°C) above space temperature and ceiling return provided that the 150 fpm (0.8 m/s) supply air jet reaches to within 4.5 ft (1.4 m) of floor level. Note: For lower velocity supply air, Ez = 0.8.	1.0
Floor supply of cool air and ceiling return provided that the 150 fpm (0.8 m/s) supply jet reaches 4.5 ft (1.4 m) or more above the floor. Note: Most underfloor air distribution systems comply with this proviso.	1.0
Floor supply of cool air and ceiling return, provided low-velocity displacement ventilation achieves unidirectional flow and thermal stratification.	1.2
Floor supply of warm air and floor return.	1.0
Floor supply of warm air and ceiling return.	0.7
Make-up supply drawn in on the opposite side of the room from the exhaust and/or return.	0.8
Make-up supply drawn in near to the exhaust and/or return location.	0.5
1. "Cool air" is air cooler than space temperature. 2. "Warm air" is air warmer than space temperature. 3. "Ceiling" includes any point above the breathing zone. 4. "Floor" includes any point below the breathing zone. 5. As an alternative to using the above values, Ez may be regarded as equal to air change effectiveness determined in accordance with ANSI/ASHRAE Standard	

Recirculation fraction

The non-negative numeric input for this field is the fraction of a zone's recirculation air that does not directly mix with the outdoor air. The zone secondary recirculation fraction Er is determined by the designer based on system configuration. For plenum return systems with secondary recirculation (e.g., fan-powered VAV with plenum return) Er is usually less than 1.0, although values may range from 0.1 to 1.2 depending upon the location of the ventilation zone relative to other zones and the air handler. For ducted return systems with secondary recirculation (e.g., fan-powered VAV with ducted return), Er is typically 0.0, while for those with system-level recirculation (e.g, dual-fan dual-duct systems with ducted return) Er is typically 1.0. For other system types, Er is typically 0.75. Minimum is 0.0, and default is 0.0 for single-path systems (also to maintain backward compatibility). For parallel fan-powered VAV systems, the secondary ventilation path only functions (Er > 0.0) when the fans in the VAV boxes operate, which is during heating. The local ventilation path and the benefits of secondary recirculation disappear during cooling, when the local parallel fans are off (Er = 0.0).

Sizing

Cooling Sizing

Cooling design supply air temperature input method

This option determines how the cooling design air flow rate is calculated in the system autosizing calculations:

- **1- Supply air temperature** means that the **Zone cooling design supply air temperature** (below) will be used to determine the zone cooling design air flow rate.
- **2-Temperature difference** where the **Zone cooling design supply air temperature difference** (below) is used to determine the zone cooling design air flow rate.

Cooling design supply air temperature

This is the supply air temperature (in °C or °F) for the zone cooling air flow rate calculation. Air is supplied to the zone at this temperature during the cooling design day simulation and the zone load is met by varying the zone air flow rate. The maximum zone flow rate is used as the zone cooling design air flow rate.

This data is only available when the Cooling design supply air temperature input method (above) is **1-Supply air temperature**.

Cooling design supply air temperature difference

The temperature difference between cooling design supply air temperature and room air temperature (in delta°C or delta°F) for the zone cooling design air flow rate calculation. Air is supplied to the zone with this temperature difference during the cooling design day autosizing simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is used as the zone cooling design air flow rate.

This data is only available when the Cooling design supply air temperature input method (above) is **2-Temperature difference**.

Cooling design supply air humidity ratio

This is the humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone cooling autosizing air flow rate calculation.

Cooling minimum air flow fraction

This is the minimum zone design cooling volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate for VAV systems only. In all cases the maximum flow derived from [Cooling minimum flow per zone floor area](#), [Cooling minimum air flow](#), and [Cooling minimum air flow fraction](#) is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. This input is currently used in sizing the fan minimum flow rate. It does not affect other component auto-sizing.

Note: This value is only used when the zone is connected to a VAV Air loop, in which case this data is used for sizing and not for the simulation itself.

Zone cooling sizing factor

This is the zone level cooling sizing ratio. The zone design cooling air flow rates and loads will be multiplied by the number input in this field. The default value comes from the [Zone group dialog](#) whose default **Zone cooling sizing factor** is the ASHRAE recommended cooling oversizing factor of 1.15.

Cooling design air flow method

There are 3 options:

- **1-Design day** means the program will calculate the zone design cooling air flow rate using the zone cooling sizing information and a design day simulation without imposing any limits other than those set by the minimum outside air requirements.
- **2-Flow/zone** means that the program will use the [Cooling design air flow rate](#) as the zone design cooling air flow rate.
- **3-Design day with limit** means that the maximum from [Cooling minimum flow per zone floor area](#) and [Cooling minimum air flow](#) will set a lower limit on the design maximum cooling air flow rate.

Cooling design air flow rate

This is the design zone cooling air flow rate (in m³/s or ft³/min). This setting is only required if [Cooling design air flow method](#) is specified as **2-Flow/zone**. This value will be multiplied by the global or zone sizing factor and by zone multipliers.

Cooling minimum flow per zone floor area

This is the minimum zone cooling volumetric flow rate per square meter (units are m³/s-m²). This setting is only required if the [Cooling design air flow method](#) is specified as **3-Design day with limit**. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from [Cooling minimum flow per zone floor area](#), [Cooling minimum air flow](#), and [Cooling minimum air flow fraction](#) is used to set a minimum supply air flow rate for the zone for VAV systems. The default is 0.000762 m³/s-m², corresponding to 0.15 cfm/ft². The applicable sizing factor is not applied to this value.

Cooling minimum air flow

This is the minimum zone cooling volumetric flow rate (in m³/s). This field is used when [Cooling design air flow method](#) is specified as **3-Design day with limit**. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from [Cooling minimum flow per zone floor area](#), [Cooling minimum air flow](#), and [Cooling minimum air flow fraction](#) is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. The applicable sizing factor is not applied to this value.

Heating Sizing

Heating design supply air temperature input method

This option determines how the heating design air flow rate is calculated in the system autosizing calculations:

- **1- Supply air temperature** means that the **Zone heating design supply air temperature** (below) will be used to determine the zone heating design air flow rate.
- **2-Temperature difference** where the **Zone heating design supply air temperature difference** (below) is used to determine the zone heating design air flow rate.

Heating design supply air temperature

This is the supply air temperature (in °C or °F) for the zone heating design air flow rate calculation. Air is supplied to the zone at this temperature during the heating design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is used as the zone heating design air flow rate.

Heating design supply air temperature difference

The temperature difference between heating design supply air temperature and room air temperature (in delta°C or delta°F) for the zone heating design air flow rate calculation. Air is supplied to the zone with this temperature difference during the heating design day autosizing simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is used as the zone heating design air flow rate.

Heating design supply air humidity ratio

This is the humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone heating design air flow rate calculation.

Zone heating sizing factor

This is the zone level heating sizing ratio. The zone design heating air flow rates and loads will be multiplied by the number input in this field. The default value comes from the [Zone group dialog](#) whose default **Zone heating sizing factor** is the ASHRAE recommended heating oversizing factor of 1.25.

Heating design air flow method

There are three options:

- **1-Design day** means the program will calculate the zone design heating air flow rate using the zone heating sizing information and a design day simulation without imposing any limits other than those set by the minimum outside air requirements.
- **2-Flow/zone** means that the program will use the [Heating design air flow rate](#) as the zone design heating air flow rate.
- **3-Design day with limit** means that the maximum from [Heating maximum flow per zone floor area](#) and [Heating maximum air flow](#) will set a lower limit on the design maximum heating air flow rate.

Heating design air flow rate

This is the design zone heating air flow rate (in m³/s or ft³/min). This setting is only required if [Heating design air flow method](#) is specified as **2-Flow/zone**. This value will be multiplied by the global or zone sizing factor and by zone multipliers.

Heating maximum flow per zone floor area

This is the maximum zone heating volumetric flow rate per square metre (units are m³/s-m²). This setting is only required if the [Heating design air flow method](#) is specified as **3-DesignDayWithLimit**. In this case it sets an upper bound on the zone design heating air flow rate. In all cases the maximum flow derived from [Heating maximum flow per zone floor area](#), [Heating maximum air flow](#), and [Heating maximum air flow fraction](#) is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.002032 m³/s-m², corresponding to .40 cfm/ft². This input is not currently used for auto-sizing any of the components.

Heating maximum air flow

This is the maximum zone heating volumetric flow rate in m³/s. This setting is only required if the [Heating design air flow method](#) is specified as **3-Design day with limit**. In this case it sets an upper bound on the zone design heating air flow rate. In all cases the maximum flow derived from [Heating maximum flow per zone floor area](#), [Heating maximum air flow](#), and [Heating maximum air flow fraction](#) is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.14158 m³/s, corresponding to 300 cfm. This input is not currently used for auto-sizing any of the components.

Outdoor Air Sizing

When the [Detailed HVAC Activity data](#) is set to **1-Simple HVAC** then all data under the **Outdoor Air Sizing** header is disabled and the outdoor air requirement settings are copied from the corresponding building zones' Activity and/or HVAC model data as described below.

When the [Detailed HVAC Activity data](#) is set to **2-Detailed HVAC** then the outdoor air requirement is defined here on the HVAC zone dialog.

Outdoor air method

There are five options:

- **1-Flow/Zone**, means that the program will use the [Outdoor air flow per zone](#) as the zone design outdoor air flow rate.
- **2-Flow/Person**, means the program will use the input from the field [Outdoor air flow per person](#) and the [maximum occupancy](#) to calculate a zone design outdoor air flow rate.
- **3-Flow/Area**, means that the flows calculated from the fields [Outdoor air flow per zone floor area](#) used to obtain the zone design outdoor air flow rate.
- **4-Sum**, means that the flows calculated from the fields [Outdoor air flow per person](#), [Outdoor air flow per zone floor area](#) and [Outdoor air flow per zone](#) will be added to obtain the zone design outdoor air flow rate.

- **5-Maximum** means that the maximum flow derived from [Outdoor air flow per person](#), [Outdoor air flow per zone floor area](#) and [Outdoor air flow per zone](#) will be used for the zone design outdoor air flow rate.

Note: If the [Detailed HVAC Activity data](#) is set to **1-Simple HVAC** then this option is disabled and the **Outdoor air method** is copied from the corresponding building zones' HVAC model data.

Outdoor air flow per person

This is the design outdoor air flow rate per person for this zone (in m³/s or ft³/min). This setting is only required if either one of the **2-Flow/person**, **4-Sum**, or **5-Maximum** options have been selected for the [Outdoor air method](#). The default is 0.00944 m³/s (20 cfm per person). An outdoor air flow rate is calculated based on the total [number of people](#) assigned to the zone. Occupancy schedule values are not applied.

Note: If the [Detailed HVAC Activity data](#) is set to **1-Simple HVAC** then this option is disabled and the **Outdoor air flow per person** is copied from [Outdoor air flow per person](#) from the corresponding building zones' Activity model data.

Outdoor air flow per zone floor area

This is the design outside air volumetric flow rate per square meter of floor area (in m³/s-m²). This setting is only required if either one of the **3-Flow/area**, **4-Sum**, or **5-Maximum** options have been selected for the [Outdoor air method](#). This value is multiplied by the zone floor area to obtain a flow rate.

Note: If the [Detailed HVAC Activity data](#) is set to **1-Simple HVAC** then this option is disabled and the [Outdoor air flow per zone floor area](#) data is copied from the corresponding building zones' Activity model data.

Outdoor air flow per zone

This is the design outdoor air flow rate for this zone (in m³/s or ft³/min). This setting is only used if either one of the **1-Flow/zone**, **4-Sum**, or **5-Maximum** options have been selected for the [Outdoor air method](#).

Note: If the [Detailed HVAC Activity data](#) is set to **1-Simple HVAC** then this option is disabled and the flow per zone is calculated from the ac/h value set on the HVAC model data tab and displayed here.

Dedicated Outdoor Air System Sizing

Account for Dedicated Outdoor Air System

Checking this option means that the zone sizing calculation will use the inputs below to calculate the heat gain or loss imposed on the zone by a Dedicated Outdoor Air System (DOAS). This heat gain/loss is added to the zone design heat gain for the zone and the zone design air flow rate is adjusted to meet the DOAS heat gain plus the zone design heat gain.

Field: Dedicated Outdoor Air System Control Strategy

Select from three control strategies for the outdoor air system. The choices are:

- **1-Neutral supply air**, the default option in which ventilation air supplied to the zone will cause little heating or cooling. The air will be heated or cooled to keep it between the low and high temperature setpoints specified in the subsequent two fields. A good choice for these fields might be 21.1 and 23.9°C.
- **2-Neutral dehumidified supply air**, where the ventilation air will be cooled and dehumidified and then reheated to a neutral temperature. The ventilation air is cooled to the lower setpoint temperature (if necessary) and reheated to the upper setpoint temperature. A good choice for the setpoints would be 14.4 and 22.2°C, or
- **3-Cold supply air** where the ventilation air will be used to supply cooling to the zone. Cold outside air is heated to the upper setpoint; warm outside air is cooled to the lower setpoint. A good choice for the setpoints would be 12.2 and 14.4°C.

Low temperature setpoint for design

The lower setpoint temperature to be used with the DOAS design control strategy (in °C or °F). The default is autosized to the values given above for the three design control strategies.

High temperature setpoint for design

The higher setpoint temperature to be used with the DOAS design control strategy (in °C or °F). The default is autosized to the values given above for the three design control strategies.

Load Outdoor Air Model Data

When using the [Detailed HVAC Activity data](#) model option, 2 links are displayed on the Info panel to facilitate the copying of relevant outdoor air data from the HVAC and Activity model data tabs to the [Outdoor air sizing](#) section of the HVAC zone dialog.

Load outdoor air data to this HVAC zone only

When the [Load outdoor air data to this HVAC zone only](#) Info panel link is clicked, model data from the associated building zone is copied from the Activity and HVAC tabs to this dialog.

For example, if the Mechanical Ventilation [Outside air definition method](#) on the HVAC tab is set to **4-Min fresh air (Sum per person + per area)**, DesignBuilder will make the following settings under the **Outside Air Sizing** header of this dialog.

- [Outside air method](#) is set to **4-Sum**.
- [Outside air flow per person](#) is set based on the setting on the [Minimum fresh air per person](#) setting on the Activity tab.
- [Outside air flow per zone floor area](#) is set based on the setting on the [Mech vent per area](#) setting on the Activity tab.

Load outdoor air data to all HVAC zones

When the [Load outdoor air data to all HVAC zones](#) Info panel link is clicked, model data from the associated building zone is copied from the Activity and HVAC tabs to this dialog. Then if/when you press the OK button to confirm settings for this HVAC zone, the Outside Air Sizing data on this dialog is also copied to all other HVAC zones in the model.

Edit HVAC Zone Data - Sequence

Data on the [Sequence](#) tab defines the load distribution scheme, heating and cooling calculation sequences and sequential heating and cooling fraction schedules.

Load Distribution Scheme

Load Distribution Scheme

Select the load distribution scheme to be used for this HVAC Zone. Choose from the following options:

- **1-Sequential Load** - loads each piece of available equipment sequentially with the full remaining load.
- **2-Uniform Load** - evenly distributes the total load equally among all available components on the equipment list for the current load type.
- **3-Uniform PLR** - evenly distributes the total load among all available components on the equipment list for the current load type at a uniform part load ratio (PLR).
- **4-Sequential Uniform PLR** - determines how many of the available components are required to meet the current load, then distributes the load at a uniform part load ratio (PLR).

Heating Calculation Sequence

Each item of zone heating equipment associated with the current HVAC zone is listed under the **Heating Calculation Sequence** header. Here you can define the order that each item of equipment is simulated and hence the sequence that each item of equipment will try to meet the demand with its available capacity.

Equipment is simulated in the order specified, depending on the current thermostat request. For equipment of similar type, assign sequence 1 to the first system intended to serve that type of load, assign sequence 2 to the next system, and so on. The #1 sequence equipment will try to meet the entire demand with its available capacity and then pass the results on to #2 to meet any remaining load and so on.

For situations where one or more equipment types has limited capacity or limited control capability, order the sequence so that the most controllable piece of equipment runs last. For example, with a dedicated outdoor air system (DOAS), the air terminal for the DOAS should be assigned a sequence of 1. Any other equipment should be assigned sequence 2 or higher so that it will see the net load after the DOAS air is added to the zone.

Cooling Calculation Sequence

Each item of zone cooling equipment associated with the current HVAC zone is listed under the **Cooling Calculation Sequence** header. Here you can define the order that each item of equipment is simulated and hence the sequence that each item of equipment will try to meet the demand with its available capacity.

Equipment is simulated in the order specified, depending on the current thermostat request. For equipment of similar type, assign sequence 1 to the first system intended to serve that type of load, assign sequence 2 to the next system, and so on. The #1 sequence equipment will try to meet the entire demand with its available capacity and then pass the results on to the #2 to meet any remaining load and so on.

For situations where one or more equipment types has limited capacity or limited control capability, order the sequence so that the most controllable piece of equipment runs last. For example, with a dedicated outdoor air system (DOAS), the air terminal for the DOAS should be assigned a sequence of 1. Any other equipment should be assigned sequence 2 or higher so that it will see the net load after the DOAS air is added to the zone.

Sequential Heating Fraction Schedules

For each item of zone heating equipment associated with the current HVAC zone, select a schedule that specifies the fraction of the remaining heating load this equipment will attempt to serve. This setting is only available if the Load distribution scheme is set to **1-Sequential Load**.

Sequential Cooling Fraction Schedules

For each item of zone cooling equipment associated with the current HVAC zone, select a schedule that specifies the fraction of the remaining cooling load this equipment will attempt to serve. This setting is only available if the Load distribution scheme is set to **1-Sequential Load**.

Edit HVAC Zone Data - Target

Define HVAC Zone Affected By Changes

HVAC Zones target

By default any edits made to the HVAC Zone dialog will apply only to the current HVAC Zone. However it is often convenient to make the same changes to one or more other zones in the same HVAC Zone group. This selection allows you to control how changes are applied. Options are:

- **1-This HVAC Zone only** - the data on the dialog will be saved for the current HVAC zone only.
- **2-Multiple (all settings)** - all of the data on the dialog will be saved for all HVAC zones in the group
- **3-Multiple (modified settings only)** - only the changed settings on the dialog (shown in red) will be saved for all HVAC zones in the group.

Note: If you would like to change the default behaviour so that the equivalent objects in other HVAC zones in the same group are all ticked when dialogs are first opened then you should check the [Target all HVAC zones in group by default](#) Program option.

Setpoint Manager

To edit the data associated with a setpoint manager, you first need to select it by moving the mouse cursor over it and then clicking the mouse button to select it. You can then access the edit dialog by right-clicking the mouse and selecting the Edit selected component option or alternatively, select the Edit selected component tool from the toolbar.

Name

This is the name that you assign to the setpoint manager which should be unique. If the supplied name is not unique, the software will automatically append a backslash and number to ensure that there are no duplicate names.

Type

There several different types of setpoint manager available. However only certain types of setpoint manager are available for different types of loop:

- [1-Scheduled](#) (All loops).
- [2-Warmest](#) ([Generic](#) and [dual duct](#) air loops only).
- [3-Coldest](#) ([Generic](#) and [dual duct](#) air loops only).
- [4-Multi-zone minimum humidity average](#) (Air loops only).
- [5-Multi-zone maximum humidity average](#) (Air loops only).
- [6-Multi-zone humidity minimum](#) (Air loops only).
- [7-Multi-zone humidity maximum](#) (Air loops only).
- [8-Single zone humidity minimum](#) (Air loops only).
- [9-Single zone humidity maximum](#) (Air loops only).
- [10-Outdoor air reset](#) ([Generic](#) and [dual duct](#) air loops, plant and condenser loops).
- [11-Single zone heating](#) (Air loops only).
- [12-Single zone cooling](#) (Air loops only).
- [13-Multi-zone cooling average](#) (Air loops only).

- [14- Multi-zone heating average](#) (Air loops only).
- [15-Follow ground temperature](#) (Condenser loops only)
- [16-Follow outdoor air temperature](#)
- [17-Dual setpoint](#) (Plant loops only)

1-Scheduled Setpoint Manager

Scheduled setpoint managers are the simplest type of setpoint manager and work by placing a scheduled setpoint value at the point or connection in the loop at which the setpoint manager control line has been placed. This allows you to specify either a constant, a seasonal, or other time-varying scheduled reset control strategy.

Control variable

The control variable can be one of:

- **1-Temperature** - defines temperature of fluid at node (°C)
- **2-Maximum temperature** - defines the maximum temperature of fluid at node (°C)
- **3-Minimum temperature** - defines minimum temperature of fluid at node (°C)
- **4-Humidity ratio** - defines the humidity ratio of fluid at node (kg water/ kg dry air)
- **5-Maximum humidity ratio** - defines maximum humidity ratio of fluid at node (kg water/ kg dry air)
- **6-Minimum humidity ratio** - defines minimum humidity ratio of fluid at node (kg water/ kg dry air)
- **7-Mass flow rate** - defines mass flow rate of fluid at node (kg/s)
- **8-Maximum mass flow rate** - defines maximum mass flow rate of fluid at node (kg/s)
- **9-Minimum mass flow rate** - defines minimum mass flow rate of fluid at node (kg/s)

Setpoint variable schedule

Select a schedule whose values are to be used as setpoints on the node or node list. The schedule value for each time period is the setpoint for this type of setpoint manager. The schedule must have values that are in the appropriate units as defined in the previous field.

2-Warmest Setpoint Manager

Warmest setpoint managers are available only in Generic and Dual Duct air loops. The warmest setpoint manager resets the cooling supply air temperature of a central forced air HVAC system according to the cooling demand of the warmest zone. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone cooling load at the maximum zone supply air flow rate. The lowest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the highest supply air temperature that will meet the cooling requirements of all the zones. When compared to a fixed cooling supply air temperature setpoint, this strategy minimises zone reheat coil energy (or overcooling) and central chiller energy consumption (if the chilled water temperature is also reset) at the cost of possible increased fan energy.

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum setpoint temperature

This is the minimum allowed setpoint temperature (in °C or °F). If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum.

Maximum setpoint temperature

This is the maximum allowed setpoint temperature (in °C or °F). If the calculated setpoint is greater than this value the setpoint is set to the maximum. This value is also used as the setpoint temperature when none of the zones have a cooling load.

3-Coldest Setpoint Manager

Coldest setpoint managers are available only in Generic and Dual Duct air loops. The coldest setpoint manager is used in dual duct systems to reset the setpoint temperature of the air in the heating supply duct. Usually it is used in conjunction with a Warmest Setpoint Manager resetting the temperature of the air in the cooling supply duct. For each zone in the system at each system timestep, the manager calculates a supply air temperature that will meet the zone heating load at the maximum zone supply air flow rate. The highest of the possible supply air temperatures becomes the new supply air temperature setpoint, subject to minimum and maximum supply air temperature constraints. The resulting temperature setpoint is the lowest supply air temperature that will meet the heating requirements of all the zones. When compared to a fixed heating supply air temperature setpoint, this strategy minimises central boiler energy consumption (if the hot water temperature is also reset or there are variable speed pumps) at the cost of possible increased fan energy (if there is variable volume control in the air system).

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum setpoint temperature

This is the minimum allowed setpoint temperature (in °C or °F). If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. This value is also used as the setpoint temperature when none of the zones have a heating load.

Maximum setpoint temperature

This is the maximum allowed setpoint temperature (in °C or °F). If the calculated setpoint is greater than this value the setpoint is set to the maximum.

4-Multi-Zone Minimum Humidity Average Setpoint Manager

This setpoint manager allows for controlling the minimum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, together with humidistats which must be defined for the controlled zones, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate an average supply air humidity ratio needed to maintain the zone relative humidity levels near their respective humidifying setpoints. The calculated humidity ratio is then used as the minimum humidity ratio setpoint for the designated setpoint node(s). A humidification component (e.g. humidifier) placed upstream of the setpoint node can then use the minimum humidity ratio setpoint to control humidification rate.

Note: This setpoint manager requires that humidistats are specified for the controlled zones.

Minimum setpoint humidity ratio

This is the minimum humidity ratio (kg/kg) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value.

Maximum setpoint humidity ratio

This is the maximum humidity ratio (kg/kg) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value.

5-Multi-Zone Maximum Humidity Average Setpoint Manager

This setpoint manager allows for controlling the maximum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, together with humidistats which must be defined for the controlled zones, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate an average supply air humidity ratio needed to maintain the

zone relative humidity levels near their respective dehumidifying setpoints. The calculated humidity ratio is then used as the maximum humidity ratio setpoint for the designated setpoint node(s). A dehumidification component (e.g. water cooling coil) placed upstream of the setpoint node can then use the maximum humidity ratio setpoint to control its moisture removal rate.

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with the coil controller to determine the supply air temperature required to meet both the temperature (sensible) and humidity (latent) load in the control zone.

Note: This setpoint manager requires that humidistats are specified for the controlled zones.

Minimum setpoint humidity ratio

This is the minimum humidity ratio (kg/kg) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value.

Maximum setpoint humidity ratio

This is the maximum humidity ratio (in kg/kg) that is allowed by this set point manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value.

6-Multi-Zone Humidity Minimum Setpoint Manager

This setpoint manager allows for controlling the minimum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, together with humidistats which must be defined for the controlled zones, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate a supply air minimum humidity ratio based on a zone with the critical humidification requirement (i.e., a zone with the highest humidity ratio setpoint) to maintain the zone relative humidity levels near their respective humidifying setpoints. The calculated humidity ratio is then used as the minimum humidity ratio setpoint for the designated setpoint node(s). A humidification component (e.g. humidifier) placed upstream of the setpoint node can then use the minimum humidity ratio setpoint to control humidification rate. If a humidistat is defined for only one of the zones served by the air loop then this setpoint manager behaves in the same way as the Single Zone Humidity Minimum setpoint manager.

Note: This setpoint manager requires that humidistats are specified for the controlled zones.

Minimum setpoint humidity ratio

This is the minimum humidity ratio (kg/kg) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value.

Maximum setpoint humidity ratio

This is the maximum humidity ratio (kg/kg) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value.

7-Multi-Zone Humidity Maximum Setpoint Manager

This setpoint manager allows for controlling the maximum humidity level in multiple zones served by a central forced air HVAC system (air loop). This setpoint manager, used in conjunction with one or more Zone humidistat objects, detects the air humidity level in multiple controlled zones served by the HVAC air loop and uses air/moisture mass balances to calculate the maximum supply air humidity ratio based on a zone with the critical dehumidification requirement (i.e., a zone with the lowest humidity ratio setpoint) to maintain the zone relative humidity levels near their respective dehumidifying setpoints. The calculated humidity ratio is then used as the maximum humidity ratio setpoint for the designated setpoint node(s). A dehumidification component (e.g., desiccant dehumidifier) placed upstream of the setpoint node can then use the maximum humidity ratio setpoint to control its moisture removal rate.

The use of this object requires that a Zone Humidistat object be specified with a dehumidifying relative humidity schedule for one or more controlled zones served by the HVAC air loop. If the Zone Humidistat is defined for only one of the zones served by the air loop then this Setpoint Manager performs as a [Single zone humidity maximum setpoint manager](#).

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with the controller associated with the [Cooling coil - water](#) object to determine the supply air temperature required to meet both the temperature (sensible) and dehumidification (latent) load in the control zone.

See object Controller:WaterCoil in the EnergyPlus Engineering Reference for a detailed discussion of how this is achieved.

Minimum setpoint humidity ratio

The minimum humidity ratio (in kg/kg) that is allowed by this setpoint manager. If the calculated setpoint humidity ratio is less than this value, then the setpoint is set to this minimum value. The default value is 0.008 kg/kg.

Maximum setpoint humidity ratio

The maximum humidity ratio (in kg/kg) that is allowed by this set point manager. If the calculated setpoint humidity ratio is greater than this value, then the setpoint is set to this maximum value. The default value is 0.015 kg/kg.

8-Single Zone Humidity Minimum Setpoint Manager

The Single Zone Minimum Humidity Setpoint Manager allows the control of a single zone minimum humidity level. This setpoint manager detects the humidity level in a control zone and, using air and moisture mass balance, calculates the supply air humidity ratio needed to maintain the zone relative humidity at or above a given setpoint. The calculated supply air humidity ratio is then used as the setpoint for the designated setpoint node. A humidifier component placed upstream of the setpoint node can then use the humidity ratio setpoint to control its moisture addition rate.

Note: This setpoint manager requires that a humidistat be specified for the controlled zone.

Control zone

Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone for humidity control.

9-Single Zone Humidity Maximum Setpoint Manager

The Single Zone Maximum Humidity Setpoint Manager allows the control of a single zone maximum humidity level. This setpoint manager, together with a humidistat which must be defined for the controlled zone, detects the air humidity level in a single control zone and uses air/moisture mass balances to calculate the supply air humidity ratio needed to maintain the zone relative humidity at or below a given setpoint. The calculated supply air humidity ratio is then used as the setpoint for the designated setpoint node. A dehumidification component placed upstream of this node can then use the humidity ratio setpoint to control its moisture removal rate (e.g. water cooling coil).

In the case of a chilled water coil which is used for both temperature and high humidity control, this setpoint manager works in conjunction with the coil controller to determine the minimum supply air temperature required to meet both the temperature (sensible) and humidity (latent) load in the control zone.

Note: This setpoint manager requires that a humidistat be specified for the controlled zone.

Control zone

Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone for humidity control.

10-Outdoor Air Reset Setpoint Manager

The Outdoor Air Reset Setpoint Manager sets the supply temperature according to the outdoor air temperature using a reset rule. The reset rule is determined by 2 points: the supply setpoint temperature at the outdoor high temperature (SATO_H) and the supply setpoint temperature at the outdoor low temperature (SATO_L). If the outdoor temperature is above the outdoor high temperature, the supply temperature is set to SATO_H. If the outdoor temperature is below the outdoor low temperature, the supply temperature is set to SATO_L. If the outdoor temperature is between the outdoor high and outdoor low temperatures, the supply air temperature is linearly interpolated between SATO_H and SATO_L.

An optional second reset rule may be defined.

Note: Normally SATO_H will be lower than SATO_L in which case EnergyPlus interpolates to calculate the supply temperature. If SATO_H is higher than SATO_L then EnergyPlus sets the supply air temperature to the average of the SATO_H and SATO_L.

The default Outdoor air reset settings for various loop types are:

Loop Type	Outdoor Low Temp (°C)	Setpoint for Outdoor Low Temp (°C)	Outdoor High Temp (°C)	Setpoint for Outdoor High Temp (°C)	Comment
Air loop	0	16	15	12	
Hot water loop	5	80	15	60	
Chilled water loop	15.56	12.22	26.67	6.67	ASHRAE 90.1 Appendix G
Condenser loop	0	33	15	29	
DHW loop	5	60	15	50	

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Setpoint at outdoor low temperature

This is the setpoint (°C or °F) at the outdoor low temperature for the first reset rule.

Outdoor low temperature

This is the outdoor air low temperature (°C or °F) for the first supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its maximum.

Setpoint at outdoor high temperature

This is the setpoint temperature (°C or °F) at the outdoor high temperature for the first reset rule.

Outdoor high temperature

This is the outdoor air high temperature (°C or °F) for the first supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its minimum.

Second reset rule

This check-box allows you to define a second reset rule.

Second reset schedule

This is the schedule whose values indicate which reset rule to use for each time over the year. Schedule values of 1 indicate that the first reset rule will be used. Schedule values of 2 select the second reset rule.

Important Note: The schedule selected here must only include values of 1 or 2.

Second reset rule setpoint at outdoor low temperature

This is the setpoint temperature (°C or °F) at the outdoor low temperature for the second reset rule.

Second reset rule outdoor low temperature

This is the outdoor air low temperature (°C) for the second supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its maximum.

Second reset rule setpoint at outdoor high temperature

This is the setpoint temperature (°C or °F) at the outdoor high temperature for the second reset rule.

Second reset rule outdoor high temperature

This is the outdoor air high temperature (°C) for the second supply air temperature reset rule. Generally, at this outdoor air temperature the supply temperature is at its minimum.

11-Single Zone Heating Setpoint Manager

The Single Zone Heating Setpoint Manager allows components to be controlled based on the load required to meet the zone heating setpoint. This setpoint manager detects the control zone load to meet the current heating setpoint, zone inlet node flow rate, and zone node temperature, and calculates a setpoint temperature for the supply air that will satisfy the zone heating load for the control zone. This setpoint manager creates a variable temperature system and is normally applied only to constant volume air loops.

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum supply air temperature

The minimum supply air temperature (in °C or °F) that is allowed for this system (as set by this setpoint manager).

Maximum supply air temperature

The maximum supply air temperature (in °C or °F) that is allowed for this system (as set by this setpoint manager)

Control zone

Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone for single zone heating control.

Combining 11-Single Zone Heating and 12-Single Zone Cooling Setpoint Managers

Note: A variable temperature, constant volume heating and cooling system can be simulated by combining a **11-Single Zone Heating Setpoint Manager** with a **12-Single Zone Cooling Setpoint Manager** together on the supply side of a loop.

In this case, the temperature range setpoints entered for both heating and cooling SPMs should be identical.

The way this is done depends on whether the AHU has a blow-through or draw-through fan configuration.

Blow-through: When the fan is placed upstream of the heating and cooling coils in the AHU then the **11-Single Zone Heating Setpoint Manager** is placed directly after the heating coil, between the heating coil and the cooling coil and the **12-Single Zone Cooling Setpoint Manager** is placed downstream of the AHU.

Draw-through: When the fan is placed downstream of the heating and cooling coils in the AHU then both the **11-Single Zone Heating Setpoint Manager** and **12-Single Zone Cooling Setpoint Manager** are placed downstream of the AHU.

12-Single Zone Cooling Setpoint Manager

The Single Zone Cooling Setpoint Manager allows components to be controlled based on the load required to meet the zone cooling setpoint. This setpoint manager detects the control zone load to meet the current cooling setpoint, zone inlet node flow rate, and zone node temperature, and calculates a setpoint temperature for the supply air that will satisfy the zone cooling load for the control zone. This setpoint manager creates a variable temperature system and is normally applied only to constant volume air loops.

Note: See also the note above on [Combining 11-Single Zone Heating and 12-Single Zone Cooling Setpoint Managers](#).

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum supply air temperature

The minimum supply air temperature (in °C or °F) that is allowed for this system (as set by this setpoint manager).

Maximum supply air temperature

The maximum supply air temperature (in °C or °F) that is allowed for this system (as set by this setpoint manager).

Control zone

Click on the <Select zone> label and then click on the displayed ellipsis button to bring up the zone selector dialog. Select the zone for single zone cooling control.

13-Multi Zone Cooling Average Setpoint Manager

This SPM is commonly used in conjunction with a multi-zone heating average SPM for systems where both heating and cooling is to be provided by the central AHU with no zone reheat. It is used to establish a supply

air temperature setpoint for a central forced air HVAC system (air loop) based on the predicted sensible cooling loads and actual supply air mass flow rates for all zones served by the system. For all controlled zones in the air loop (i.e., zones with a thermostat object), the setpoint manager calculates an average supply air temperature that will meet the zone cooling loads based on the actual zone supply air mass flow rates (lagged by one time step). The calculated setpoint temperature is subject to the minimum and maximum setpoint temperature constraints specified by the user. When compared to a fixed cooling supply air temperature setpoint, this strategy may reduce zone reheat coil energy (or overcooling) and central chiller energy consumption (if the chilled water temperature is also reset) at the cost of possible increased fan energy.

Note: this SPM is intended for use on constant volume air loops only

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum setpoint temperature

The minimum supply air temperature (in °C or °F) that is allowed for this system. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. The default value is 12°C.

Maximum setpoint temperature

The maximum supply air temperature (in °C or °F) that is allowed for this system. If the calculated setpoint temperature is greater than this value, the setpoint is set to this maximum value. The default value is 18°C.

Note: The same notes for combining single zone heating and cooling SPMs apply to the multizone equivalents. See [Combining 11-Single Zone Heating and 12-Single Zone Cooling Setpoint Managers](#).

14-Multi Zone Heating Average Setpoint Manager

This setpoint manager is used to establish a supply air temperature setpoint for a central forced air HVAC system (air loop) based on the predicted sensible heating loads and actual supply air mass flow rates for all zones served by the system. For all controlled zones in the air loop (i.e., zones with a thermostat object), the setpoint manager calculates an average supply air temperature that will meet the zone heating loads based on the actual zone supply air mass flow rates (lagged by one time step). The calculated setpoint temperature is subject to the minimum and maximum setpoint temperature constraints specified by the user. When compared to a fixed heating supply air temperature setpoint, this strategy may reduce central boiler energy consumption (if the hot water temperature is also reset or there are variable speed pumps) at the cost of possible increased fan energy (if there is variable volume control for the air system).

Note: this SPM is intended for use on constant volume air loops only

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum setpoint temperature

The minimum supply air temperature (in °C or °F) that is allowed for this system. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. The default value is 20°C.

Maximum setpoint temperature

The maximum supply air temperature (in °C or °F) that is allowed for this system. If the calculated setpoint temperature is greater than this value, the setpoint is set to this maximum value. The default value is 50°C.

Note: The same notes for combining single zone heating and cooling SPMs apply to the multizone equivalents. See [Combining 11-Single Zone Heating and 12-Single Zone Cooling Setpoint Managers](#).

15-Follow Ground Temperature

This setpoint manager provides a temperature setpoint on a system node that is derived from a current ground temperature. The ground temperatures are specified in at site level and used during the simulation. This setpoint manager is primarily intended for condenser or plant loops using some type of ground heat exchanger.

When this SPM is selected the following other fields should be defined.

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum setpoint temperature

The minimum supply air temperature (in °C or °F) that is allowed for this system. If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum. The default value is 11°C.

Maximum setpoint temperature

The maximum supply air temperature (in °C or °F) that is allowed for this system. If the calculated setpoint temperature is greater than this value, the setpoint is set to this maximum value. The default value is 16°C.

Reference ground temperature

This setting specifies the type of ground temperature to be used by the setpoint manager. There are four options:

- 1-Deep** - uses the [Deep monthly temperatures](#) defined at site level.
- 2-Shallow** - uses the [Shallow monthly temperatures](#) defined at site level.
- 3-Building surface** - uses the [Monthly ground temperatures](#) defined at site level.

Tip: Generally the deep ground temperatures are the most useful for a plant loop serving a vertical borehole ground heat exchanger.

Offset temperature difference

This data provides a temperature offset that will be applied to the value of the ground temperature. If this value is zero, and the limits are met, then the resulting setpoint will be exactly the same as the ground temperature. The sign convention is that a positive value here will increase the resulting setpoint to higher than the ground temperature.

16-Follow Outdoor Air Temperature

This setpoint manager is used to place a temperature setpoint on a system node that is derived from the current outdoor air environmental conditions. The outdoor air conditions are obtained from the weather information during the simulation.

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Minimum setpoint temperature

This is the minimum allowed setpoint temperature (in °C or °F). If the calculated setpoint temperature is less than this minimum, the setpoint is set to the minimum.

Maximum setpoint temperature

This is the maximum allowed setpoint temperature (in °C or °F). If the calculated setpoint is greater than this value the setpoint is set to the maximum. This value is also used as the setpoint temperature when none of the zones have a cooling load.

Offset temperature difference

This is a temperature offset that will be applied to the value of the reference temperature (outdoor air wetbulb/drybulb). If this value is zero, and the limits are met, then the resulting setpoint will be exactly the same as the outdoor air wetbulb/drybulb temperature. The sign convention is that a positive value here will increase the resulting setpoint to higher than the outdoor air wetbulb/drybulb.

17-Dual Setpoint

This setpoint manager places a high and low schedule value on one or more nodes. The input consists of the Setpoint Manager name, the control variable, the high and low set point schedule names.

The Dual Setpoint manager can be used with Plant loops only and can be used to create a mixed water loop to give both heating and cooling setpoints on the same loop. In this case settings on the [Plant Equipment Operation](#) tab of the Plant loop dialog define which equipment has priority depending on whether there is a heating or cooling load.

The Dual Setpoint manager should be used together with the **2-DualSetPoint** [Plant loop demand calculation scheme](#) option.

When this SPM is selected the following other fields should be defined.

Control variable

The type of variable that will be controlled. There is only one choice for this type of setpoint manager: **1-Temperature**.

Low setpoint schedule

Select the schedule that contains the low setpoint values. The schedule value for each time period is the low setpoint.

High setpoint schedule

Select the schedule that contains the high setpoint values. The schedule value for each time period is the high setpoint.

DHW

Domestic Hot Water (DHW) is provided in DesignBuilder Detailed HVAC through [DHW loops](#), [Water heaters](#), [Water outlet groups](#) and [Water outlet](#) components.

DHW loops are added at the HVAC System level. On the demand side of the DHW sub loops, Water outlet groups can be added. However a default Water outlet group is provided with the initial DHW loop so in many cases you will not need to add a new Water outlet group. Instead simply navigate to the default Water outlet

group and add one or more Water outlet components to define hot water consumption and any heat transfer to a building zone.

If you are working with the default **1-Simple HVAC** [Detailed HVAC Activity data](#) model option then simply associate the zones to be connected on the Zones served tab of the dialog. In many cases this would be all occupied zones in the building. In this case the amount of DHW consumed is calculated as a function of the activity in the zone. For example, there is a demand assumed to arise from the occupants of an office for activities such as washing hands and washing up cups. This demand is associated with the office rather than the toilet or tea room. So the demand from each space needs to be assigned to a DHW system even if the DHW delivery (tap, shower etc) is not present in the space.

On the other hand, when using the **2-Detailed HVAC** [Detailed HVAC Activity data](#) model option it would normally make more sense to model the actual water draw off rates in the rooms where hot water is consumed (toilet, tea room, shower room etc).

Tip: For consistency with Simple HVAC use the default **1-Simple HVAC** [Detailed HVAC Activity data](#) model option then create a single DHW loop, use the default [Water outlet group](#) and [Water outlet](#) provided with the [DHW loop](#) and select all zones in the building on the [Zones served](#) tab of the Water outlet.

The DHW-related Detailed HVAC components are:

- [Water Outlet Group](#)
- [Water Outlet](#)
- [Water Heater Data](#)

Water Outlet Group

The Water outlet group component is used to group Water outlet components and connect them to a Water heater. Water outlet groups are placed on the demand sub loop of a DHW loop as shown in the screenshot above.

To add new [Water outlets](#) to a Water outlet group first navigate to the Water outlet group and then use the Add water outlet toolbar option. You can edit the details for each Water outlet by right clicking on it in the Water outlet group screen image and selecting the Edit drop down menu option.

Drain Water Heat Exchanger

Drain water heat exchanger type

The heat exchanger type to be used for drain water heat recovery. The options are:

1-None indicating no heat recovery is to be simulated.

2-Ideal sets a heat exchanger effectiveness of 1.0.

3-Counter flow where effectiveness is calculated dynamically

4-Cross flow where effectiveness is calculated dynamically.

One popular type of drain water heat exchanger is the Gravity-Film Heat Exchanger (GFX). The GFX is most closely approximated with the **3-Counter flow** option, but keep in mind that the UA varies more with flow rate for the GFX than for most traditional heat exchangers.

Drain water heat exchanger destination

The heat exchanger configuration to be used for drain water heat recovery. The configuration determines where the heat will be used after it is recovered. The options are:

- **1-Plant** which indicates that the all of the recovered heat will be sent to the return flow at the outlet node of the [Water outlets](#) to preheat the make-up cold water from the water mains.
- **2-Equipment**, indicating that the all of the recovered heat will be used to preheat the cold water flow side of the [Water outlets](#) listed in this Water outlet group
- **3-Plant and Equipment**, indicating that the recovered heat will be divided between the plant and the [Water outlets](#), as described above. This is the only option where the flow rates are equal in the drain and the heat exchanger.

Drain water heat exchanger UA

The UA is the heat transfer coefficient (in W/K or Btu/h-F) for the heat exchanger. It is the product of U, the overall heat transfer coefficient, and A, the heat exchanger surface area.

Water Outlet

The Water outlet component defines hot water consumption, delivery temperatures as well as any heat conduction and latent gains to zones. One or more Water outlets can be associated with a previously defined [Water outlet group](#).

The way that Water outlets works in very different depending on whether you are using the Simple or Detailed HVAC [Detailed HVAC Activity data](#) setting.

Simple HVAC Activity data
